where  $z = \frac{(\pi)}{4} + (zeta)$ ,  $(zeta) = \sqrt[3]{-x}$  and  $a(t)$  and  $b(t)$  are expansions in the variable  $t = -2 \sqrt[5]{x} - 1$ .

For  $-5 \leq x \leq 0$ ,

$$Bi'(x) = \sqrt[3]{x} (f(t) + g(t)),$$

where  $f$  and  $g$  are expansions in  $t = -2 \sqrt[5]{x} - 1$ .

For  $0 < x < 4.5$ ,

$$Bi'(x) = e^{3x/2} y(t),$$

where  $y(t)$  is an expansion in  $t = 4x/9 - 1$ .

For  $4.5 \leq x < 9$ ,

$$Bi'(x) = e^{21x/8} u(t),$$

where  $u(t)$  is an expansion in  $t = 4x/9 - 3$ .

For  $x \geq 9$ ,

$$Bi'(x) = \sqrt[4]{x} e^z v(t),$$

where  $z = \sqrt[3]{x}$  and  $v(t)$  is an expansion in  $t = 2 \sqrt[3]{x} - 1$ .

For  $|x| <$  the square of the machine precision, the result is set directly to  $Bi'(0)$ . This saves time and avoids possible underflows in calculation.

For large negative arguments, it becomes impossible to calculate a result for the oscillating function with any accuracy so the

4/7

(            )  
(    \/(pi)   )

routine must fail. This occurs for  $x < -$ ( -----) , where  
(epsilon))

(epsilon) is the machine precision.

For large positive arguments, where  $Bi'$  grows in an essentially exponential manner, there is a danger of overflow so the routine must fail.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
On entry: the argument x of the function.
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
X is too large and positive. On soft failure the routine returns zero.

IFAIL= 2  
X is too large and negative. On soft failure the routine returns zero.

#### 7. Accuracy

For negative arguments the function is oscillatory and hence

absolute error is appropriate. In the positive region the function has essentially exponential behaviour and hence relative error is needed. The absolute error, E, and the relative error (epsilon), are related in principle to the relative error in the argument (delta), by

$$E \sim |x \operatorname{Bi}(x)| (\delta) \quad (\epsilon) \sim \frac{|x^2 \operatorname{Bi}(x)|}{|\operatorname{Bi}'(x)|} (\delta).$$

In practice, approximate equality is the best that can be expected. When (delta), (epsilon) or E is of the order of the machine precision, the errors in the result will be somewhat larger.

For small x, positive or negative, errors are strongly attenuated by the function and hence will effectively be bounded by the machine precision.

For moderate to large negative x, the error is, like the function, oscillatory. However, the amplitude of the absolute

error grows like  $|x|^{7/4}$ . Therefore it becomes impossible to

$$\sqrt[7]{\pi}$$

calculate the function with any accuracy if  $|x|^{7/4} \sqrt[7]{\pi} > (\delta)$ .

For large positive x, the relative error amplification is

considerable:  $(\epsilon) \sim \frac{(\delta)^3}{\sqrt[7]{x}}$ . However, very large arguments are not possible due to the danger of overflow. Thus in practice the actual amplification that occurs is limited.

## 8. Further Comments

None.

## 9. Example

The example program reads values of the argument x from a file,

evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17DCF  
 S17DCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S17DCF returns a sequence of values for the Bessel functions  $Y_{\nu}(z)$  for complex  $z$ , non-negative ( $\nu$ ) and  $n=0,1,\dots,N-1$ ,  $(\nu)+n$  with an option for exponential scaling.

### 2. Specification

```

      SUBROUTINE S17DCF (FNU, Z, N, SCALE, CY, NZ, CWRK, IFAIL)
      INTEGER          N, NZ, IFAIL
      DOUBLE PRECISION FNU
      COMPLEX(KIND(1.0D0)) Z, CY(N), CWRK(N)
      CHARACTER*1      SCALE
  
```

### 3. Description

This subroutine evaluates a sequence of values for the Bessel function  $Y_{\nu}(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq (\pi)$ , and  $(\nu)$

$(\nu)$  is the real, non-negative order. The  $N$ -member sequence is generated for orders  $(\nu)$ ,  $(\nu)+1, \dots, (\nu)+N-1$ . Optionally, the

sequence is scaled by the factor  $e^{-|\operatorname{Im} z|}$ .

Note: although the routine may not be called with  $(\nu)$  less than zero, for negative orders the formula

$Y_{-(\nu)}(z) = Y_{\nu}(z) \cos((\pi)(\nu)) + J_{\nu}(z) \sin((\pi)(\nu))$  may be used  
 (for the Bessel function  $J_{\nu}(z)$ , see S17DEF).

The routine is derived from the routine CBESY in Amos [2]. It is

(1) (2)

based on the relation 
$$Y_{(\nu)}(z) = \frac{H_{(\nu)}(z) - H_{(\nu)}(z)}{2i}, \text{ where } H_{(\nu)}(z) \quad (1)$$

(2)  
and  $H_{(\nu)}(z)$  are the Hankel functions of the first and second kinds respectively (see S17DLF).

When  $N$  is greater than 1, extra values of  $Y_{(\nu)}(z)$  are computed using recurrence relations.

For very large  $|z|$  or  $((\nu)+N-1)$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$  or  $((\nu)+N-1)$ , the computation is performed but results are accurate to less than half of machine precision. If  $|z|$  is very small, near the machine underflow threshold, or  $((\nu)+N-1)$  is too large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.
- [2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

#### 5. Parameters

- 1: FNU -- DOUBLE PRECISION Input  
On entry: the order,  $(\nu)$ , of the first member of the sequence of functions. Constraint: FNU  $\geq 0.0$ .
- 2: Z -- COMPLEX(KIND(1.0D0)) Input  
On entry: the argument,  $z$ , of the functions. Constraint: Z  $\neq (0.0, 0.0)$ .
- 3: N -- INTEGER Input  
On entry: the number,  $N$ , of members required in the sequence  $Y_{(\nu)}(z), Y_{(\nu)+1}(z), \dots, Y_{(\nu)+N-1}(z)$ . Constraint:  $N \geq 1$ .
- 4: SCALE -- CHARACTER\*1 Input  
On entry: the scaling option.

If SCALE = 'U', the results are returned unscaled.

If `SCALE = 'S'`, the results are returned scaled by the  
 $-|\text{Im}z|$   
 factor  $e^{\quad}$ . Constraint: `SCALE = 'U' or 'S'`.

5: `CY(N) -- COMPLEX(KIND(1.0D)) array` Output  
 On exit: the `N` required function values: `CY(i)` contains  
 $Y(z)$ , for  $i=1,2,\dots,N$ .  
 $(nu)+i-1$

6: `NZ -- INTEGER` Output  
 On exit: the number of components of `CY` that are set to zero  
 due to underflow. The positions of such components in the  
 array `CY` are arbitrary.

7: `CWRK(N) -- COMPLEX(KIND(1.0D)) array` Workspace

8: `IFAIL -- INTEGER` Input/Output  
 On entry: `IFAIL` must be set to 0, -1 or 1. For users not  
 familiar with this parameter (described in the Essential  
 Introduction) the recommended value is 0.

On exit: `IFAIL = 0` unless the routine detects an error (see  
 Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry `IFAIL = 0` or -1, explanatory error messages are  
 output on the current error message unit (as defined by `X04AAF`).

`IFAIL= 1`

On entry `FNU < 0.0`,

or  $Z = (0.0, 0.0)$ ,

or  $N < 1$ ,

or `SCALE /= 'U' or 'S'`.

`IFAIL= 2`

No computation has been performed due to the likelihood of  
 overflow, because  $\text{ABS}(Z)$  is less than a machine-dependent  
 threshold value (given in the Users' Note for your  
 implementation).

`IFAIL= 3`

No computation has been performed due to the likelihood of  
 overflow, because  $FNU + N - 1$  is too large - how large

depends on  $Z$  as well as the overflow threshold of the machine.

IFAIL= 4

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by S17DCF are accurate to less than half of machine precision. This error exit may occur if either  $\text{ABS}(Z)$  or  $\text{FNU} + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S17DCF would be lost. This error exit may occur if either  $\text{ABS}(Z)$  or  $\text{FNU} + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 6

No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DCF would have caused overflow or underflow.

## 7. Accuracy

All constants in subroutine S17DCF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S17DCF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s = \max(1, \log_{10} |z|, \log_{10} (\text{nu}))$  represents the number of digits

lost due to the argument reduction. Thus the larger the values of  $|z|$  and  $(\text{nu})$ , the less the precision in the result. If S17DCF is called with  $N > 1$ , then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S17DCF with different base values of  $(\text{nu})$  and different  $N$ , the computed values may not agree exactly. Empirical tests with modest values of  $(\text{nu})$  and  $z$  have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

## 8. Further Comments

The time taken by the routine for a call of S17DCF is approximately proportional to the value of  $N$ , plus a constant. In general it is much cheaper to call S17DCF with  $N$  greater than 1, rather than to make  $N$  separate calls to S17DCF.

Paradoxically, for some values of  $z$  and  $(nu)$ , it is cheaper to call S17DCF with a larger value of  $N$  than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different  $N$ , and the costs in each region may differ greatly.

Note that if the function required is  $Y_0(x)$  or  $Y_1(x)$ , i.e.,  $(nu) = 0$  or  $1$ , where  $x$  is real and positive, and only a single unscaled function value is required, then it may be much cheaper to call S17ACF or S17ADF respectively.

#### 9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the order FNU, the second is a complex value for the argument,  $Z$ , and the third is a value for the parameter SCALE. The program calls the routine with  $N = 2$  to evaluate the function for orders FNU and FNU + 1, and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17DEF  
 S17DEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S17DEF returns a sequence of values for the Bessel functions  $J_n(z)$  for complex  $z$ , non-negative  $(nu)$  and  $n=0,1,\dots,N-1$ ,  $(nu)+n$

with an option for exponential scaling.

## 2. Specification

```

SUBROUTINE S17DEF (FNU, Z, N, SCALE, CY, NZ, IFAIL)
  INTEGER          N, NZ, IFAIL
  DOUBLE PRECISION FNU
  COMPLEX(KIND(1.0D0)) Z, CY(N)
  CHARACTER*1      SCALE

```

## 3. Description

This subroutine evaluates a sequence of values for the Bessel function  $J_{(\text{nu})}(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq (\pi)$ , and  $(\text{nu})$  is the real, non-negative order. The  $N$ -member sequence is generated for orders  $(\text{nu})$ ,  $(\text{nu})+1, \dots, (\text{nu})+N-1$ . Optionally, the sequence is scaled by the factor  $e^{-|\text{Im } z|}$ .

Note: although the routine may not be called with  $(\text{nu})$  less than zero, for negative orders the formula  $J_{-(\text{nu})}(z) = J_{(\text{nu})}(z) \cos((\pi)(\text{nu})) - Y_{(\text{nu})}(z) \sin((\pi)(\text{nu}))$  may be used (for the Bessel function  $Y_{(\text{nu})}(z)$ , see S17DCF).

The routine is derived from the routine CBESJ in Amos [2]. It is based on the relations  $J_{(\text{nu})}(z) = e^{(\text{nu})(\pi)i/2} I_{(\text{nu})}(-iz)$ ,  $\text{Im } z \geq 0.0$  and  $J_{(\text{nu})}(z) = e^{-(\text{nu})(\pi)i/2} I_{(\text{nu})}(iz)$ ,  $\text{Im } z < 0.0$ .

The Bessel function  $I_{(\text{nu})}(z)$  is computed using a variety of techniques depending on the region under consideration.

When  $N$  is greater than 1, extra values of  $J_{(\text{nu})}(z)$  are computed using recurrence relations.

For very large  $|z|$  or  $((\text{nu})+N-1)$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$  or  $((\text{nu})+N-1)$ , the computation is performed but results are accurate to less than half of machine precision. If  $\text{Im } z$  is large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

## 5. Parameters

- 1: FNU -- DOUBLE PRECISION Input  
On entry: the order, (nu), of the first member of the sequence of functions. Constraint: FNU >= 0.0.
  
- 2: Z -- COMPLEX(KIND(1.0D0)) Input  
On entry: the argument z of the functions.
  
- 3: N -- INTEGER Input  
On entry: the number, N, of members required in the sequence  
J (z), J (z), ..., J (z). Constraint: N >= 1.  
(nu) (nu)+1 (nu)+N-1
  
- 4: SCALE -- CHARACTER\*1 Input  
On entry: the scaling option.  
If SCALE = 'U', the results are returned unscaled.  
  
If SCALE = 'S', the results are returned scaled by the  
-|Imz|  
factor e .  
Constraint: SCALE = 'U' or 'S'.
  
- 5: CY(N) -- COMPLEX(KIND(1.0D0)) array Output  
On exit: the N required function values: CY(i) contains  
J (z), for i=1,2,...,N.  
(nu)+i-1
  
- 6: NZ -- INTEGER Output  
On exit: the number of components of CY that are set to zero due to underflow. If NZ > 0, then elements CY(N-NZ+1), CY(N-NZ+2), ..., CY(N) are set to zero.
  
- 7: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry  $IFAIL = 0$  or  $-1$ , explanatory error messages are output on the current error message unit (as defined by  $X04AAF$ ).

$IFAIL = 1$

On entry  $FNU < 0.0$ ,

or  $N < 1$ ,

or  $SCALE \neq 'U'$  or  $'S'$ .

$IFAIL = 2$

No computation has been performed due to the likelihood of overflow, because  $\text{Im } Z$  is larger than a machine-dependent threshold value (given in the Users' Note for your implementation). This error exit can only occur when  $SCALE = 'U'$ .

$IFAIL = 3$

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by  $S17DEF$  are accurate to less than half of machine precision. This error exit may occur if either  $\text{ABS}(Z)$  or  $FNU + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

$IFAIL = 4$

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by  $S17DEF$  would be lost. This error exit may occur when either  $\text{ABS}(Z)$  or  $FNU + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

$IFAIL = 5$

No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to  $S17DEF$  would have caused overflow or underflow.

## 7. Accuracy

All constants in subroutine  $S17DEF$  are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the

maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S17DEF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s = \max(1, \log_{10}(|z|), \log_{10}(\nu))$  represents the number of digits

lost due to the argument reduction. Thus the larger the values of  $|z|$  and  $(\nu)$ , the less the precision in the result. If S17DEF is called with  $N > 1$ , then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S17DEF with different base values of  $(\nu)$  and different  $N$ , the computed values may not agree exactly. Empirical tests with modest values of  $(\nu)$  and  $z$  have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

#### 8. Further Comments

The time taken by the routine for a call of S17DEF is approximately proportional to the value of  $N$ , plus a constant. In general it is much cheaper to call S17DEF with  $N$  greater than 1, rather than to make  $N$  separate calls to S17DEF.

Paradoxically, for some values of  $z$  and  $(\nu)$ , it is cheaper to call S17DEF with a larger value of  $N$  than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different  $N$ , and the costs in each region may differ greatly.

Note that if the function required is  $J_0(x)$  or  $J_1(x)$ , i.e.,  $(\nu) = 0.0$  or  $1.0$ , where  $x$  is real and positive, and only a single unscaled function value is required, then it may be much cheaper to call S17AEF or S17AFF respectively.

#### 9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the order FNU, the second is a complex value for the argument,  $Z$ , and the third is a value for the parameter SCALE.

The program calls the routine with  $N = 2$  to evaluate the function for orders FNU and FNU + 1, and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17DGF  
 S17DGF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S17DGF returns the value of the Airy function  $Ai(z)$  or its derivative  $Ai'(z)$  for complex  $z$ , with an option for exponential scaling.

### 2. Specification

```
SUBROUTINE S17DGF (DERIV, Z, SCALE, AI, NZ, IFAIL)
  INTEGER          NZ, IFAIL
  COMPLEX(KIND(1.0D0)) Z, AI
  CHARACTER*1      DERIV, SCALE
```

### 3. Description

This subroutine returns a value for the Airy function  $Ai(z)$  or its derivative  $Ai'(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq (\pi)$ .

Optionally, the value is scaled by the factor  $e^{2z\sqrt{z}/3}$ .

The routine is derived from the routine CAIRY in Amos [2]. It is

based on the relations  $Ai(z) = \frac{\sqrt{z} K_{1/3}(w)}{1/3}$ , and  $Ai'(z) = \frac{-z K_{2/3}(w)}{2/3}$ ,

$(\pi)\sqrt{3}$   $(\pi)/3$

where  $K_{(\nu)}$  is the modified Bessel function and  $w=2z\sqrt{z}/3$ .

For very large  $|z|$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$ , the computation is performed but results are accurate to less than half of machine precision. If  $\text{Re } w$  is too large, and the unscaled function is required, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.
- [2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

#### 5. Parameters

- 1: DERIV -- CHARACTER\*1 Input  
 On entry: specifies whether the function or its derivative is required.  
 If DERIV = 'F',  $Ai(z)$  is returned.  
 If DERIV = 'D',  $Ai'(z)$  is returned.  
 Constraint: DERIV = 'F' or 'D'.
- 2: Z -- COMPLEX(KIND(1.0D0)) Input  
 On entry: the argument  $z$  of the function.
- 3: SCALE -- CHARACTER\*1 Input  
 On entry: the scaling option.  
 If SCALE = 'U', the result is returned unscaled.  
 If SCALE = 'S', the result is returned scaled by the factor  $e^{2z\sqrt{z}/3}$ .  
 Constraint: SCALE = 'U' or 'S'.
- 4: AI -- COMPLEX(KIND(1.0D0)) Output  
 On exit: the required function or derivative value.
- 5: NZ -- INTEGER Output  
 On exit: NZ indicates whether or not AI is set to zero due to underflow. This can only occur when SCALE = 'U'.  
 If NZ = 0, AI is not set to zero.

If  $NZ = 1$ ,  $AI$  is set to zero.

6: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry DERIV /= 'F' or 'D'.

or SCALE /= 'U' or 'S'.

IFAIL= 2

No computation has been performed due to the likelihood of

overflow, because  $\text{Re } w$  is too large, where  $w = 2Z/Z/3$  -- how large depends on  $Z$  and the overflow threshold of the machine. This error exit can only occur when SCALE = 'U'.

IFAIL= 3

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the result returned by S17DGF is accurate to less than half of machine precision. This error exit may occur if  $\text{ABS}(Z)$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 4

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in the result returned by S17DGF would be lost. This error exit may occur if  $\text{ABS}(Z)$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5

No result is returned because the algorithm termination condition has not been met. This may occur because the

parameters supplied to S17DGF would have caused overflow or underflow.

#### 7. Accuracy

All constants in subroutine S17DGF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S17DGF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s \sim \max(1, |\log_{10} |z||)$  represents the number of digits lost due to the argument reduction. Thus the larger the value of  $|z|$ , the less the precision in the result.

Empirical tests with modest values of  $z$ , checking relations between Airy functions  $Ai(z)$ ,  $Ai'(z)$ ,  $Bi(z)$  and  $Bi'(z)$ , have shown errors limited to the least significant 3-4 digits of precision.

#### 8. Further Comments

Note that if the function is required to operate on a real argument only, then it may be much cheaper to call S17AGF or S17AJF.

#### 9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the parameter DERIV, the second is a complex value for the argument,  $Z$ , and the third is a value for the parameter SCALE. The program calls the routine and prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17DHF  
S17DHF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details.

The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S17DHF returns the value of the Airy function  $\text{Bi}(z)$  or its derivative  $\text{Bi}'(z)$  for complex  $z$ , with an option for exponential scaling.

### 2. Specification

```
SUBROUTINE S17DHF (DERIV, Z, SCALE, BI, IFAIL)
  INTEGER          IFAIL
  COMPLEX(KIND(1.0D0)) Z, BI
  CHARACTER*1      DERIV, SCALE
```

### 3. Description

This subroutine returns a value for the Airy function  $\text{Bi}(z)$  or its derivative  $\text{Bi}'(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq (\pi)$ .

Optionally, the value is scaled by the factor  $e^{\frac{1}{3}\text{Re}(2z\sqrt{z/3})}$ .

The routine is derived from the routine CBIRY in Amos [2]. It is

based on the relations  $\text{Bi}(z) = \frac{\sqrt{z}}{\sqrt{3}} \left( I_{-1/3}(w) + I_{1/3}(w) \right)$ , and

$$\text{Bi}'(z) = \frac{z}{\sqrt{3}} \left( I_{-2/3}(w) + I_{2/3}(w) \right), \text{ where } I_{\nu} \text{ is the modified Bessel function and } w = 2z\sqrt{z/3}.$$

function and  $w = 2z\sqrt{z/3}$ .

For very large  $|z|$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$ , the computation is performed but results are accurate to less than half of machine precision. If  $\text{Re } z$  is too large, and the unscaled function is required, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

### 4. References

- [2] Hammersley J M and Handscomb D C (1967) Monte-Carlo Methods. Methuen.

## 5. Parameters

- 1: DERIV -- CHARACTER\*1 Input  
 On entry: specifies whether the function or its derivative is required.  
 If DERIV = 'F', Bi(z) is returned.  
  
 If DERIV = 'D', Bi'(z) is returned.  
 Constraint: DERIV = 'F' or 'D'.
- 2: Z -- COMPLEX(KIND(1.0D0)) Input  
 On entry: the argument z of the function.
- 3: SCALE -- CHARACTER\*1 Input  
 On entry: the scaling option.  
 If SCALE = 'U', the result is returned unscaled.  
  
 If SCALE = 'S', the result is returned scaled by the  
  

$$\frac{|\operatorname{Re}(2z\sqrt{z/3})|}{\operatorname{factor} e}.$$
 Constraint: SCALE = 'U' or 'S'.
- 4: BI -- COMPLEX(KIND(1.0D0)) Output  
 On exit: the required function or derivative value.
- 5: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry DERIV /= 'F' or 'D'.

or SCALE /= 'U' or 'S'.

IFAIL= 2

No computation has been performed due to the likelihood of overflow, because  $\text{real}(Z)$  is too large - how large depends on the overflow threshold of the machine. This error exit can only occur when SCALE = 'U'.

IFAIL= 3

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the result returned by S17DHF is accurate to less than half of machine precision. This error exit may occur if  $\text{ABS}(Z)$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 4

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in the result returned by S17DHF would be lost. This error exit may occur if  $\text{ABS}(Z)$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5

No result is returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DHF would have caused overflow or underflow.

## 7. Accuracy

All constants in subroutine S17DHF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S17DHF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s \sim \max(1, |\log |z||)$  represents the number of digits lost due to

10

the argument reduction. Thus the larger the value of  $|z|$ , the less the precision in the result.

Empirical tests with modest values of  $z$ , checking relations between Airy functions  $\text{Ai}(z)$ ,  $\text{Ai}'(z)$ ,  $\text{Bi}(z)$  and  $\text{Bi}'(z)$ , have shown errors limited to the least significant 3-4 digits of precision.

## 8. Further Comments

Note that if the function is required to operate on a real argument only, then it may be much cheaper to call S17AHF or S17AKF.

## 9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the parameter DERIV, the second is a complex value for the argument, Z, and the third is a value for the parameter SCALE. The program calls the routine and prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17DLF  
 S17DLF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

S17DLF returns a sequence of values for the Hankel functions

(1) (2)  
 H (z) or H (z) for complex z, non-negative (nu) and  
 (nu)+n (nu)+n  
 n=0,1,...,N-1, with an option for exponential scaling.

## 2. Specification

```

SUBROUTINE S17DLF (M, FNU, Z, N, SCALE, CY, NZ, IFAIL)
  INTEGER          M, N, NZ, IFAIL
  DOUBLE PRECISION FNU
  COMPLEX(KIND(1.0D0)) Z, CY(N)
  CHARACTER*1      SCALE

```

## 3. Description

This subroutine evaluates a sequence of values for the Hankel

function  $H_{(\nu)}^{(1)}(z)$  or  $H_{(\nu)}^{(2)}(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq (\pi)$ , and  $(\nu)$  is the real, non-negative order. The  $N$ -member sequence is generated for orders  $(\nu)$ ,  $(\nu)+1, \dots, (\nu)+N-1$ .

Optionally, the sequence is scaled by the factor  $e^{-iz}$  if the function is  $H_{(\nu)}^{(1)}(z)$  or by the factor  $e^{iz}$  if the function is  $H_{(\nu)}^{(2)}(z)$ .

$H_{(\nu)}^{(1)}(z)$ .

Note: although the routine may not be called with  $(\nu)$  less than zero, for negative orders the formulae

$H_{(\nu)}^{(1)}(z) = e^{(\nu)(\pi)i} H_{(\nu)}^{(1)}(z)$ , and  $H_{(\nu)}^{(2)}(z) = e^{-(\nu)(\pi)i} H_{(\nu)}^{(2)}(z)$  may be used.

The routine is derived from the routine CBESH in Amos [2]. It is based on the relation

$$H_{(\nu)}^{(m)}(z) = -e^{\frac{1}{2}p(\nu)} K_{(\nu)}^{(p)}(ze^{\frac{1}{2}p(\nu)}),$$

where  $p=i$  if  $m=1$  and  $p=-i$  if  $m=2$ , and the Bessel function  $K_{(\nu)}(z)$  is computed in the right half-plane only.

Continuation of  $K_{(\nu)}(z)$  to the left half-plane is computed in terms of the Bessel function  $I_{(\nu)}(z)$ . These functions are evaluated using a variety of different techniques, depending on the region under consideration.

When  $N$  is greater than 1, extra values of  $H_{(\nu)}^{(m)}(z)$  are computed using recurrence relations.

For very large  $|z|$  or  $((\nu)+N-1)$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$  or  $((\nu)+N-1)$ , the computation is performed but results are accurate to less than half of machine precision. If  $|z|$  is very small, near the machine underflow threshold, or

$((\text{nu})+N-1)$  is too large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

- [2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

#### 5. Parameters

- 1: M -- INTEGER Input  
 On entry: the kind of functions required.  

(1)

 If M = 1, the functions are  $H_{(\text{nu})}(z)$ .  

(2)

 If M = 2, the functions are  $H_{(\text{nu})}(z)$ .  

(nu)

 Constraint: M = 1 or 2.
- 2: FNU -- DOUBLE PRECISION Input  
 On entry: the order, (nu), of the first member of the sequence of functions. Constraint: FNU  $\geq$  0.0.
- 3: Z -- COMPLEX(KIND(1.0D0)) Input  
 On entry: the argument z of the functions. Constraint: Z  $\neq$  (0.0, 0.0).
- 4: N -- INTEGER Input  
 On entry: the number, N, of members required in the sequence  
 $H_{(M)}^{(M)}, H_{(M)}^{(M)}, \dots, H_{(M)}^{(M)}$ . Constraint: N  $\geq$  1.  
 $H_{(\text{nu})}^{(\text{nu})}, H_{(\text{nu})+1}^{(\text{nu})+1}, \dots, H_{(\text{nu})+N-1}^{(\text{nu})+N-1}$
- 5: SCALE -- CHARACTER\*1 Input  
 On entry: the scaling option.  
 If SCALE = 'U', the results are returned unscaled.  
  
 If SCALE = 'S', the results are returned scaled by the  

$e^{-iz}$   $e^{iz}$

 factor  $e^{-iz}$  when M = 1, or by the factor  $e^{iz}$  when M = 2.  
 Constraint: SCALE = 'U' or 'S'.

- 6: CY(N) -- COMPLEX(KIND(1.0D)) array Output  
 On exit: the N required function values: CY(i) contains  
 (M)  
 H , for  $i=1,2,\dots,N$ .  
 (nu)+i-1
- 7: NZ -- INTEGER Output  
 On exit: the number of components of CY that are set to zero  
 due to underflow. If  $NZ > 0$ , then if  $\text{Im}z > 0.0$  and  $M = 1$ , or  
 $\text{Im}z < 0.0$  and  $M = 2$ , elements CY(1), CY(2), ..., CY(NZ) are set  
 to zero. In the complementary half-planes, NZ simply states  
 the number of underflows, and not which elements they are.
- 8: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not  
 familiar with this parameter (described in the Essential  
 Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see  
 Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are  
 output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry  $M \neq 1$  and  $M \neq 2$ ,  
  
 or  $\text{FNU} < 0.0$ ,  
  
 or  $Z = (0.0, 0.0)$ ,  
  
 or  $N < 1$ ,  
  
 or  $\text{SCALE} \neq \text{'U' or 'S'}$ .

IFAIL= 2

No computation has been performed due to the likelihood of  
 overflow, because  $\text{ABS}(Z)$  is less than a machine-dependent  
 threshold value (given in the Users' Note for your  
 implementation).

IFAIL= 3

No computation has been performed due to the likelihood of  
 overflow, because  $\text{FNU} + N - 1$  is too large - how large  
 depends on Z and the overflow threshold of the machine.

## IFAIL= 4

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by S17DLF are accurate to less than half of machine precision. This error exit may occur if either  $\text{ABS}(Z)$  or  $\text{FNU} + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

## IFAIL= 5

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S17DLF would be lost. This error exit may occur when either of  $\text{ABS}(Z)$  or  $\text{FNU} + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

## IFAIL= 6

No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DLF would have caused overflow or underflow.

## 7. Accuracy

All constants in subroutine S17DLF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S17DLF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s = \max(1, \log_{10} |z|, \log_{10} (\text{nu}))$  represents the number of digits lost due to the argument reduction. Thus the larger the values of  $|z|$  and  $(\text{nu})$ , the less the precision in the result. If S17DLF is called with  $N > 1$ , then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S17DLF with different base values of  $(\text{nu})$  and different  $N$ , the computed values may not agree exactly. Empirical tests with modest values of  $(\text{nu})$  and  $z$  have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

## 8. Further Comments

The time taken by the routine for a call of S17DLF is approximately proportional to the value of  $N$ , plus a constant. In

general it is much cheaper to call S17DLF with N greater than 1, rather than to make N separate calls to S17DLF.

Paradoxically, for some values of z and (nu), it is cheaper to call S17DLF with a larger value of N than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different N, and the costs in each region may differ greatly.

### 9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the kind of function, M, the second is a value for the order FNU, the third is a complex value for the argument, Z, and the fourth is a value for the parameter SCALE. The program calls the routine with N = 2 to evaluate the function for orders FNU and FNU + 1, and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S18 -- Approximations of Special Functions S18ACF  
 S18ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S18ACF returns the value of the modified Bessel Function  $K(x)$ ,  
0  
 via the routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S18ACF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

### 3. Description

This routine evaluates an approximation to the modified Bessel Function of the second kind  $K_0(x)$ .

0

Note:  $K_0(x)$  is undefined for  $x \leq 0$  and the routine will fail for such arguments.

The routine is based on five Chebyshev expansions:

For  $0 < x \leq 1$ ,

$$K_0(x) = -\ln x \sum_{r=0}^{\infty} a_r T_r(t) + \sum_{r=0}^{\infty} b_r T_r(t), \text{ where } t = 2x^2 - 1;$$

For  $1 < x \leq 2$ ,

$$K_0(x) = e^{-x} \sum_{r=0}^{\infty} c_r T_r(t), \text{ where } t = 2x - 3;$$

For  $2 < x \leq 4$ ,

$$K_0(x) = e^{-x} \sum_{r=0}^{\infty} d_r T_r(t), \text{ where } t = x - 3;$$

For  $x > 4$ ,

$$K_0(x) = \frac{e^{-x}}{\sqrt{x}} \sum_{r=0}^{\infty} e_r T_r(t), \text{ where } t = \frac{9-x}{1+x}.$$

For  $x$  near zero,  $K_0(x) \sim -(\gamma) - \ln(x)$ , where  $(\gamma)$  denotes Euler's constant.

This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision.

For large  $x$ , where there is a danger of underflow due to the smallness of  $K_0$ , the result is set exactly to zero.

0

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

## 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument x of the function. Constraint: X > 0.  
 0.
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 X <= 0.0, K is undefined. On soft failure the routine  
 0  
 returns zero.

## 7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

$$(\epsilon) \sim \frac{|xK(x)|}{|K(x)|} (\delta).$$

Figure 1 shows the behaviour of the error amplification factor

$$\frac{|xK(x)|}{|K(x)|}$$

Figure 1

Please see figure in printed Reference Manual

However, if  $(\delta)$  is of the same order as machine precision, then rounding errors could make  $(\epsilon)$  slightly larger than the above relation predicts.

For small  $x$ , the amplification factor is approximately  $\frac{1}{\ln x}$ , which implies strong attenuation of the error, but in general  $(\epsilon)$  can never be less than the machine precision.

For large  $x$ ,  $(\epsilon) \sim x(\delta)$  and we have strong amplification of the relative error. Eventually  $K$ , which is asymptotically

$e^{-x}$  given by  $---$ , becomes so small that it cannot be calculated

$\sqrt{x}$  without underflow and hence the routine will return zero. Note that for large  $x$  the errors will be dominated by those of the Fortran intrinsic function EXP.

#### 8. Further Comments

For details of the time taken by the routine see the appropriate the Users' Note for your implementation.

#### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S18 -- Approximations of Special Functions S18ADF  
S18ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

S18ADF returns the value of the modified Bessel Function  $K(x)$ ,  
 1  
 via the routine name.

## 2. Specification

```
DOUBLE PRECISION FUNCTION S18ADF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

## 3. Description

This routine evaluates an approximation to the modified Bessel  
 Function of the second kind  $K(x)$ .

1

Note:  $K(x)$  is undefined for  $x \leq 0$  and the routine will fail for  
 1  
 such arguments.

The routine is based on five Chebyshev expansions:

For  $0 < x \leq 1$ ,

$$K(x) = \frac{1}{x} \ln x + \sum_{r=0}^{\infty} a_r T_r(t) - x \sum_{r=0}^{\infty} b_r T_r(t), \text{ where } t = 2x - 1;$$

For  $1 < x \leq 2$ ,

$$K(x) = e^{-x} \sum_{r=0}^{\infty} c_r T_r(t), \text{ where } t = 2x - 3;$$

For  $2 < x \leq 4$ ,

$$K(x) = e^{-x} \sum_{r=0}^{\infty} d_r T_r(t), \text{ where } t = x - 3;$$

For  $x > 4$ ,

$$K(x) = \frac{e^{-x}}{x} \sum_{r=0}^{\infty} e_r T_r(t), \text{ where } t = \frac{9-x}{x}.$$

$$\frac{1}{\sqrt{x}} \quad r=0 \quad \frac{1}{1+x}$$

For  $x$  near zero,  $K(x) \sim -\frac{1}{x}$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision. For very small  $x$  on some machines, it is impossible to calculate  $-\frac{1}{x}$  without overflow and the routine must fail.

For large  $x$ , where there is a danger of underflow due to the smallness of  $K$ , the result is set exactly to zero.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument  $x$  of the function. Constraint:  $X > 0$ .  
 0.
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 $X \leq 0.0$ ,  $K$  is undefined. On soft failure the routine  
 1  
 returns zero.

IFAIL= 2  
 $X$  is too small, there is a danger of overflow. On soft failure the routine returns approximately the largest representable value.

#### 7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

$$(\epsilon) \sim \left| \frac{xK(x) - K(x)}{K(x)} \right| (\delta).$$

Figure 1 shows the behaviour of the error amplification factor

$$\left| \frac{xK(x) - K(x)}{K(x)} \right|.$$

Figure 1  
Please see figure in printed Reference Manual

However if (delta) is of the same order as the machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

For small x, (epsilon) ~ (delta) and there is no amplification of errors.

For large x, (epsilon) ~ x(delta) and we have strong amplification of the relative error. Eventually  $\frac{1}{e^{-x}}$ , which is asymptotically

given by  $\frac{1}{e^{-x}}$ , becomes so small that it cannot be calculated

without underflow and hence the routine will return zero. Note that for large x the errors will be dominated by those of the Fortran intrinsic function EXP.

## 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

## 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S18 -- Approximations of Special Functions S18AEF  
 S18AEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

S18AEF returns the value of the modified Bessel Function  $I_0(x)$ ,  
 $I_0$   
 via the routine name.

## 2. Specification

```
DOUBLE PRECISION FUNCTION S18AEF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

## 3. Description

This routine evaluates an approximation to the modified Bessel Function of the first kind  $I_0(x)$ .  
 $I_0$

Note:  $I_0(-x) = I_0(x)$ , so the approximation need only consider  $x \geq 0$ .  
 $I_0$   $I_0$

The routine is based on three Chebyshev expansions:

For  $0 < x \leq 4$ ,

$$I_0(x) = e^{x^2/4} \sum_{r=0}^{\infty} \frac{a_r}{r!} T_r(t), \text{ where } t = 2(x^2 - 1)^{-1/2};$$

$x \rightarrow t$   $(x)$   
 $r=0$   $(4)$

For  $4 < x \leq 12$ ,

$$I(x) = e^{x^2} \int_0^x b T(t) dt, \text{ where } t = \frac{x-8}{4};$$

$r=0$

For  $x > 12$ ,

$$I(x) = \frac{e^x}{\sqrt{x}} \int_0^x c T(t) dt, \text{ where } t = 2\left(\frac{x}{12}\right) - 1.$$

$r=0$

For small  $x$ ,  $I(x) \sim 1$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision.

For large  $x$ , the routine must fail because of the danger of overflow in calculating  $e^x$ .

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
On entry: the argument  $x$  of the function.
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

X is too large. On soft failure the routine returns the approximate value of  $I(x)$  at the nearest valid argument.

0

## 7. Accuracy

Let  $(\delta)$  and  $(\epsilon)$  be the relative errors in the argument and result respectively.

If  $(\delta)$  is somewhat larger than the machine precision (i.e., if  $(\delta)$  is due to data errors etc), then  $(\epsilon)$  and  $(\delta)$  are approximately related by:

$$(\epsilon) \sim \frac{|xI(x)|}{|I(x)|} (\delta).$$

Figure 1 shows the behaviour of the error amplification factor

$$\frac{|xI(x)|}{|I(x)|}$$

Figure 1

Please see figure in printed Reference Manual

However if  $(\delta)$  is of the same order as machine precision, then rounding errors could make  $(\epsilon)$  slightly larger than the above relation predicts.

For small  $x$  the amplification factor is approximately  $\frac{x^2}{2}$ , which implies strong attenuation of the error, but in general  $(\epsilon)$  can never be less than the machine precision.

For large  $x$ ,  $(\epsilon) \sim x(\delta)$  and we have strong amplification of errors. However the routine must fail for quite moderate values of  $x$ , because  $I(x)$  would overflow; hence in practice the

loss of accuracy for large  $x$  is not excessive. Note that for large  $x$  the errors will be dominated by those of the Fortran intrinsic function EXP.

## 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

# 9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S18 -- Approximations of Special Functions S18AFF  
S18AFF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

S18AFF returns a value for the modified Bessel Function  $I_1(x)$ ,  
via the routine name.

## 2. Specification

```
DOUBLE PRECISION FUNCTION S18AFF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

## 3. Description

This routine evaluates an approximation to the modified Bessel Function of the first kind  $I_1(x)$ .

Note:  $I_1(-x) = -I_1(x)$ , so the approximation need only consider  $x \geq 0$

The routine is based on three Chebyshev expansions:

For  $0 < x \leq 4$ ,

$$I_1(x) = x \sum_{r=0}^{\infty} a_r T_r(t), \text{ where } t = 2\left(\frac{x}{4}\right)^2 - 1;$$

For  $4 < x \leq 12$ ,

$$I(x) = e^{-x} \int_0^x b T(t) dt, \text{ where } t = \frac{x-8}{4};$$

For  $x > 12$ ,

$$I(x) = \frac{e^{-x}}{\sqrt{x}} \int_0^{\sqrt{x}} c T(t) dt, \text{ where } t = 2(\sqrt{x} - 1).$$

For small  $x$ ,  $I(x) \sim x$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision.

For large  $x$ , the routine must fail because  $I(x)$  cannot be represented without overflow.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
On entry: the argument  $x$  of the function.
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

- IFAIL= 1  
X is too large. On soft failure the routine returns the approximate value of  $I(x)$  at the nearest valid argument.

## 7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

$$(\epsilon) \sim \left| \frac{xI(x) - I(x)}{I(x)} \right| (\delta).$$

Figure 1 shows the behaviour of the error amplification factor

$$\left| \frac{xI(x) - I(x)}{I(x)} \right|,$$

Figure 1

Please see figure in printed Reference Manual

However if (delta) is of the same order as machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

For small x, (epsilon)~=(delta) and there is no amplification of errors.

For large x, (epsilon)~=x(delta) and we have strong amplification of errors. However the routine must fail for quite moderate values of x because I (x) would overflow; hence in practice the

1

loss of accuracy for large x is not excessive. Note that for large x, the errors will be dominated by those of the Fortran intrinsic function EXP.

## 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

## 9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S18 -- Approximations of Special Functions S18DCF  
 S18DCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S18DCF returns a sequence of values for the modified Bessel functions  $K_{\nu}(z)$  for complex  $z$ , non-negative  $(\nu)$  and  $(\nu)+n$   $n=0,1,\dots,N-1$ , with an option for exponential scaling.

### 2. Specification

```

SUBROUTINE S18DCF (FNU, Z, N, SCALE, CY, NZ, IFAIL)
  INTEGER          N, NZ, IFAIL
  DOUBLE PRECISION FNU
  COMPLEX(KIND(1.0D0)) Z, CY(N)
  CHARACTER*1      SCALE

```

### 3. Description

This subroutine evaluates a sequence of values for the modified Bessel function  $K_{\nu}(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq (\pi)$ , and  $(\nu)$  is the real, non-negative order. The  $N$ -member sequence is generated for orders  $(\nu)$ ,  $(\nu)+1, \dots, (\nu)+N-1$ .

Optionally, the sequence is scaled by the factor  $e^{\frac{z}{2}}$ .

The routine is derived from the routine CBESK in Amos [2].

Note: although the routine may not be called with  $(\nu)$  less than zero, for negative orders the formula  $K_{-\nu}(z) = K_{\nu}(z)$  may be used.

When  $N$  is greater than 1, extra values of  $K_{\nu}(z)$  are computed using recurrence relations.

For very large  $|z|$  or  $((nu)+N-1)$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$  or  $((nu)+N-1)$ , the computation is performed but results are accurate to less than half of machine precision. If  $|z|$  is very small, near the machine underflow threshold, or  $((nu)+N-1)$  is too large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.
- [2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

#### 5. Parameters

- 1: FNU -- DOUBLE PRECISION Input  
On entry: the order, (nu), of the first member of the sequence of functions. Constraint: FNU  $\geq$  0.0.
- 2: Z -- COMPLEX(KIND(1.0D0)) Input  
On entry: the argument z of the functions. Constraint: Z  $\neq$  (0.0, 0.0).
- 3: N -- INTEGER Input  
On entry: the number, N, of members required in the sequence  $K_{(nu)}(z)$ ,  $K_{(nu)+1}(z)$ , ...,  $K_{(nu)+N-1}(z)$ . Constraint: N  $\geq$  1.
- 4: SCALE -- CHARACTER\*1 Input  
On entry: the scaling option.  
  
If SCALE = 'U', the results are returned unscaled.  
  
If SCALE = 'S', the results are returned scaled by the  
factor  $e^{\frac{z}{2}}$ . Constraint: SCALE = 'U' or 'S'.
- 5: CY(N) -- COMPLEX(KIND(1.0D0)) array Output  
On exit: the N required function values: CY(i) contains  $K_{(nu)+i-1}(z)$ , for  $i=1,2,\dots,N$ .
- 6: NZ -- INTEGER Output  
On exit: the number of components of CY that are set to zero

due to underflow. If  $NZ > 0$  and  $Rez \geq 0.0$ , elements  $CY(1), CY(2), \dots, CY(NZ)$  are set to zero. If  $Rez < 0.0$ ,  $NZ$  simply states the number of underflows, and not which elements they are.

7: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry  $FNU < 0.0$ ,

or  $Z = (0.0, 0.0)$ ,

or  $N < 1$ ,

or  $SCALE \neq 'U' \text{ or } 'S'$ .

IFAIL= 2

No computation has been performed due to the likelihood of overflow, because  $ABS(Z)$  is less than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 3

No computation has been performed due to the likelihood of overflow, because  $FNU + N - 1$  is too large - how large depends on  $Z$  and the overflow threshold of the machine.

IFAIL= 4

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by S18DCF are accurate to less than half of machine precision. This error exit may occur if either  $ABS(Z)$  or  $FNU + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S18DCF would be lost. This error exit may occur when either  $\text{ABS}(Z)$  or  $\text{FNU} + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 6

No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S18DCF would have caused overflow or underflow.

## 7. Accuracy

All constants in subroutine S18DCF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S18DCF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s = \max(1, \log_{10} |z|, \log_{10} (\text{nu}))$  represents the number of digits

lost due to the argument reduction. Thus the larger the values of  $|z|$  and  $(\text{nu})$ , the less the precision in the result. If S18DCF is called with  $N > 1$ , then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S18DCF with different base values of  $(\text{nu})$  and different  $N$ , the computed values may not agree exactly. Empirical tests with modest values of  $(\text{nu})$  and  $z$  have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

## 8. Further Comments

The time taken by the routine for a call of S18DCF is approximately proportional to the value of  $N$ , plus a constant. In general it is much cheaper to call S18DCF with  $N$  greater than 1, rather than to make  $N$  separate calls to S18DCF.

Paradoxically, for some values of  $z$  and  $(\text{nu})$ , it is cheaper to call S18DCF with a larger value of  $N$  than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for

different  $N$ , and the costs in each region may differ greatly.

Note that if the function required is  $K_0(x)$  or  $K_1(x)$ , i.e.,  
 $(\text{nu})=0.0$  or  $1.0$ , where  $x$  is real and positive, and only a single function value is required, then it may be much cheaper to call  $S18ACF$ ,  $S18ADF$ ,  $S18CCF(*)$  or  $S18CDF(*)$ , depending on whether a scaled result is required or not.

### 9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the order  $FNU$ , the second is a complex value for the argument,  $Z$ , and the third is a value for the parameter  $SCALE$ . The program calls the routine with  $N = 2$  to evaluate the function for orders  $FNU$  and  $FNU + 1$ , and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S18 -- Approximations of Special Functions S18DEF  
 S18DEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S18DEF returns a sequence of values for the modified Bessel functions  $I_\nu(z)$  for complex  $z$ , non-negative  $(\text{nu})$  and  $(\text{nu})+n$   
 $n=0,1,\dots,N-1$ , with an option for exponential scaling.

### 2. Specification

```
SUBROUTINE S18DEF (FNU, Z, N, SCALE, CY, NZ, IFAIL)
  INTEGER          N, NZ, IFAIL
  DOUBLE PRECISION FNU
  COMPLEX(KIND(1.0D0)) Z, CY(N)
  CHARACTER*1      SCALE
```

### 3. Description

This subroutine evaluates a sequence of values for the modified Bessel function  $I_{(\text{nu})}(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq (\pi)$ , and  $(\text{nu})$  is the real, non-negative order. The N-member sequence is generated for orders  $(\text{nu})$ ,  $(\text{nu})+1, \dots, (\text{nu})+N-1$ .

Optionally, the sequence is scaled by the factor  $e^{-|\text{Re} z|}$ .

The routine is derived from the routine CBESI in Amos [2].

Note: although the routine may not be called with  $(\text{nu})$  less than zero, for negative orders the formula

$$I_{(\text{nu})}(z) = I_{(\text{nu})}(z) + \frac{1}{2} \sin((\pi)(\text{nu})) K_{(\text{nu})}(z)$$

may be used (for the Bessel function  $K_{(\text{nu})}(z)$ , see S18DCF).

When  $N$  is greater than 1, extra values of  $I_{(\text{nu})}(z)$  are computed using recurrence relations.

For very large  $|z|$  or  $((\text{nu})+N-1)$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$  or  $((\text{nu})+N-1)$ , the computation is performed but results are accurate to less than half of machine precision. If  $\text{Re}(z)$  is too large and the unscaled function is required, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

#### 4. References

- [2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

#### 5. Parameters

- 1: FNU -- DOUBLE PRECISION Input  
On entry: the order,  $(\text{nu})$ , of the first member of the sequence of functions. Constraint:  $\text{FNU} \geq 0.0$ .
- 2: Z -- COMPLEX(KIND(1.0D0)) Input  
On entry: the argument  $z$  of the functions.
- 3: N -- INTEGER Input

On entry: the number,  $N$ , of members required in the sequence  
 $I_{(z)}$ ,  $I_{(z)}$ , ...,  $I_{(z)}$ . Constraint:  $N \geq 1$ .  
 $(nu)$   $(nu)+1$   $(nu)+N-1$

4: SCALE -- CHARACTER\*1 Input  
 On entry: the scaling option.  
 If SCALE = 'U', the results are returned unscaled.

If SCALE = 'S', the results are returned scaled by the  
 $-|ReZ|$   
 factor  $e$ .  
 Constraint: SCALE = 'U' or 'S'.

5: CY(N) -- COMPLEX(KIND(1.0D)) array Output  
 On exit: the  $N$  required function values: CY( $i$ ) contains  
 $I_{(z)}$ , for  $i=1,2,\dots,N$ .  
 $(nu)+i-1$

6: NZ -- INTEGER Output  
 On exit: the number of components of CY that are set to zero  
 due to underflow.

If  $NZ > 0$ , then elements CY( $N-NZ+1$ ), CY( $N-NZ+2$ ), ..., CY( $N$ ) are  
 set to zero.

7: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not  
 familiar with this parameter (described in the Essential  
 Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see  
 Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are  
 output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry FNU < 0.0,

or  $N < 1$ ,

or SCALE /= 'U' or 'S'.

IFAIL= 2

No computation has been performed due to the likelihood of  
 overflow, because real(Z) is greater than a machine-

dependent threshold value (given in the Users' Note for your implementation). This error exit can only occur when  $SCALE = 'U'$ .

#### IFAIL= 3

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by S18DEF are accurate to less than half of machine precision. This error exit may occur when either  $ABS(Z)$  or  $FNU + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

#### IFAIL= 4

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S18DEF would be lost. This error exit may occur when either  $ABS(Z)$  or  $FNU + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

#### IFAIL= 5

No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S18DEF would have caused overflow or underflow.

### 7. Accuracy

All constants in subroutine S18DEF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S18DEF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s = \max(1, \log_{10} |z|, \log_{10} (nu))$  represents the number of digits

lost due to the argument reduction. Thus the larger the values of  $|z|$  and  $(nu)$ , the less the precision in the result. If S18DEF is called with  $N > 1$ , then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S18DEF with different base values of  $(nu)$  and different  $N$ , the computed values may not agree exactly. Empirical tests with modest values of  $(nu)$  and  $z$  have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

## 8. Further Comments

The time taken by the routine for a call of S18DEF is approximately proportional to the value of N, plus a constant. In general it is much cheaper to call S18DEF with N greater than 1, rather than to make N separate calls to S18DEF.

Paradoxically, for some values of z and (nu), it is cheaper to call S18DEF with a larger value of N than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different N, and the costs in each region may differ greatly.

Note that if the function required is  $I_0(x)$  or  $I_1(x)$ , i.e., (nu)=0.0 or 1.0, where x is real and positive, and only a single function value is required, then it may be much cheaper to call S18AEF, S18AFF, S18CEF(\*) or S18CFF(\*), depending on whether a scaled result is required or not.

## 9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the order FNU, the second is a complex value for the argument, Z, and the third is a value for the parameter SCALE. The program calls the routine with N = 2 to evaluate the function for orders FNU and FNU + 1, and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S19 -- Approximations of Special Functions S19AAF  
 S19AAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

S19AAF returns a value for the Kelvin function ber x via the

routine name.

## 2. Specification

```
DOUBLE PRECISION FUNCTION S19AAF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

## 3. Description

This routine evaluates an approximation to the Kelvin function `berx`.

Note: `ber(-x)=berx`, so the approximation need only consider `x>=0.0`.

The routine is based on several Chebyshev expansions:

For  $0 \leq x \leq 5$ ,

```
--'          ( x)4
berx= >  a T (t) with t=2( -) -1;
--  r r          ( 5)
r=0
```

For  $x > 5$ ,

$$\text{berx} = \frac{e^{x/\sqrt{2}} [(1 + \frac{1}{x}) \cos(\alpha) + \frac{1}{x} \sin(\alpha)]}{\sqrt{2}(\pi)x}$$

$$+ \frac{e^{-x/\sqrt{2}} [(1 + \frac{1}{x}) \sin(\beta) + \frac{1}{x} \cos(\beta)]}{\sqrt{2}(\pi)x}$$

where  $(\alpha) = \frac{x}{\sqrt{2}} \frac{(\pi)}{8}$ ,  $(\beta) = \frac{x}{\sqrt{2}} \frac{(\pi)}{8} + \frac{1}{2}$ ,

and  $a(t)$ ,  $b(t)$ ,  $c(t)$ , and  $d(t)$  are expansions in the variable

```
t= ---1.
      x
```

When  $x$  is sufficiently close to zero, the result is set directly to  $\text{ber } 0=1.0$ .

For large  $x$ , there is a danger of the result being totally inaccurate, as the error amplification factor grows in an essentially exponential manner; therefore the routine must fail.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

1: X -- DOUBLE PRECISION Input  
On entry: the argument  $x$  of the function.

2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
On entry ABS(X) is too large for an accurate result to be returned. On soft failure, the routine returns zero.

#### 7. Accuracy

Since the function is oscillatory, the absolute error rather than the relative error is important. Let  $E$  be the absolute error in the result and  $(\delta)$  be the relative error in the argument. If  $(\delta)$  is somewhat larger than the machine precision, then we have:

$$E \sim \left| \frac{x}{1 + \frac{1}{\sqrt{2}}} \right| (\text{ber } x + \text{bei } x) (\delta)$$

(provided  $E$  is within machine bounds).

For small  $x$  the error amplification is insignificant and thus the absolute error is effectively bounded by the machine precision.

For medium and large  $x$ , the error behaviour is oscillatory and

its amplitude grows like 
$$\frac{1}{\sqrt{2\pi}} e^{x/\sqrt{2}}.$$
 Therefore it is not

possible to calculate the function with any accuracy when

$$\frac{x/\sqrt{2}}{\sqrt{2\pi}} > \frac{1}{(\text{delta})}.$$
 Note that this value of  $x$  is much smaller than

the minimum value of  $x$  for which the function overflows.

## 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

## 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S19 -- Approximations of Special Functions S19ABF  
S19ABF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

S19ABF returns a value for the Kelvin function  $\text{bei } x$  via the routine name.

## 2. Specification

```

DOUBLE PRECISION FUNCTION S19ABF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X

```

### 3. Description

This routine evaluates an approximation to the Kelvin function  $\text{bei}_x$ .

Note:  $\text{bei}(-x)=\text{bei}_x$ , so the approximation need only consider  $x \geq 0.0$ .

The routine is based on several Chebyshev expansions:

For  $0 \leq x \leq 5$ ,

$$\text{bei } x = \frac{x^2}{4} \int_0^1 \frac{1}{r^2} a(T(t)) dt, \quad \text{with } t = 2\left(\frac{x}{5}\right)^4 - 1;$$

For  $x > 5$ ,

$$\text{bei } x = \frac{e^{x/\sqrt{2}}}{\sqrt{2(\pi)x}} \frac{[(1 - a(t))\sin(\alpha) - \frac{1}{x}b(t)\cos(\alpha)]}{[(1 - c(t))\cos(\beta) - \frac{1}{x}d(t)\sin(\beta)]}$$

$$+ \frac{e^{x/\sqrt{2}}}{\sqrt{2(\pi)x}} [(1 - c(t))\cos(\beta) - \frac{1}{x}d(t)\sin(\beta)]$$

$$\text{where } \alpha = \frac{x}{\sqrt{2}} \frac{(\pi)}{8}, \quad \beta = \frac{x}{\sqrt{2}} \frac{(\pi)}{8} + \frac{x}{\sqrt{2}} \frac{(\pi)}{8},$$

and  $a(t)$ ,  $b(t)$ ,  $c(t)$ , and  $d(t)$  are expansions in the variable

$$t = \frac{10}{x} - 1.$$

When  $x$  is sufficiently close to zero, the result is computed as

$$\frac{x^2}{4}$$

bei  $x = --$ . If this result would underflow, the result returned is

$$\frac{x^4}{4}$$

beix=0.0.

For large  $x$ , there is a danger of the result being totally inaccurate, as the error amplification factor grows in an essentially exponential manner; therefore the routine must fail.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument  $x$  of the function.
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

- IFAIL= 1  
 On entry ABS(X) is too large for an accurate result to be returned. On soft failure, the routine returns zero.

#### 7. Accuracy

Since the function is oscillatory, the absolute error rather than the relative error is important. Let  $E$  be the absolute error in the function, and  $(\delta)$  be the relative error in the argument. If  $(\delta)$  is somewhat larger than the machine precision, then we have:

$$E \sim \frac{x}{\sqrt{2}} \frac{1}{1} \frac{1}{1} (\delta)$$

(provided E is within machine bounds).

For small x the error amplification is insignificant and thus the absolute error is effectively bounded by the machine precision.

For medium and large x, the error behaviour is oscillatory and

its amplitude grows like  $\frac{1}{\sqrt{x}} e^{x\sqrt{2}}$ . Therefore it is

impossible to calculate the functions with any accuracy when

$\frac{x\sqrt{2}}{\sqrt{x}} > \frac{1}{\epsilon}$ . Note that this value of x is much smaller than  
(delta)

the minimum value of x for which the function overflows.

#### 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

#### 9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S19 -- Approximations of Special Functions S19ACF  
S19ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S19ACF returns a value for the Kelvin function  $\ker x$ , via the routine name.

## 2. Specification

```
DOUBLE PRECISION FUNCTION S19ACF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

## 3. Description

This routine evaluates an approximation to the Kelvin function  $\ker x$ .

Note: for  $x < 0$  the function is undefined and at  $x = 0$  it is infinite so we need only consider  $x > 0$ .

The routine is based on several Chebyshev expansions:

For  $0 < x \leq 1$ ,

$$\ker x = -f(t)\log x + \frac{(\pi)^2}{16} x g(t) + y(t)$$

where  $f(t)$ ,  $g(t)$  and  $y(t)$  are expansions in the variable  $t = 2x - 1$ ;

For  $1 < x \leq 3$ ,

$$\ker x = \exp\left(-\frac{(11)}{(16)}x\right)q(t)$$

where  $q(t)$  is an expansion in the variable  $t = x - 2$ ;

For  $x > 3$ ,

$$\ker x = \frac{(\pi)^{-x/\sqrt{2}}}{\sqrt{2x}} e^{\frac{1}{2x}} \begin{bmatrix} (1 - c(t))\cos(\beta) - \frac{1}{x}d(t)\sin(\beta) \\ (1 + c(t))\cos(\beta) - \frac{1}{x}d(t)\sin(\beta) \end{bmatrix}$$

where  $\beta = \frac{x}{8} + \frac{(\pi)}{8}$ , and  $c(t)$  and  $d(t)$  are expansions in the

variable  $t = \frac{\sqrt{2}}{6}x - 1$ .

x

When x is sufficiently close to zero, the result is computed as

$$\text{ker } x = -(\gamma) - \log\left(\frac{x}{2}\right) + \left(\frac{\pi}{8}\right) - \frac{x^2}{16} + \dots$$

and when x is even closer to zero, simply as

$$\text{ker } x = -(\gamma) - \log\left(\frac{x}{2}\right).$$

For large x,  $\text{ker } x$  is asymptotically given by  $\frac{(\pi/2) - x/\sqrt{2}}{2x} e^{-x/\sqrt{2}}$  and

this becomes so small that it cannot be computed without underflow and the routine fails.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument x of the function. Constraint: X > 0.
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 On entry X is too large, the result underflows. On soft failure, the routine returns zero.

IFAIL= 2

On entry  $X \leq 0$ , the function is undefined. On soft failure the routine returns zero.

### 7. Accuracy

Let  $E$  be the absolute error in the result,  $(\text{epsilon})$  be the relative error in the result and  $(\text{delta})$  be the relative error in the argument. If  $(\text{delta})$  is somewhat larger than the machine precision, then we have:

$$E \sim \left| \frac{x}{\sqrt{2}} \frac{\text{ker } x + \text{kei } x}{1} \right| (\text{delta}),$$

$$(\text{epsilon}) \sim \left| \frac{x}{\sqrt{2}} \frac{\text{ker } x + \text{kei } x}{\text{ker } x} \right| (\text{delta}).$$

For very small  $x$ , the relative error amplification factor is

approximately given by  $\frac{1}{|\log x|}$ , which implies a strong attenuation of relative error. However,  $(\text{epsilon})$  in general cannot be less than the machine precision.

For small  $x$ , errors are damped by the function and hence are limited by the machine precision.

For medium and large  $x$ , the error behaviour, like the function itself, is oscillatory, and hence only the absolute accuracy for the function can be maintained. For this range of  $x$ , the

amplitude of the absolute error decays like  $\frac{1}{\sqrt{x}} \frac{(\pi)x^{-x/\sqrt{2}}}{2} e^{-x/\sqrt{2}}$

which implies a strong attenuation of error. Eventually,  $\text{ker } x$ ,

which asymptotically behaves like  $\frac{1}{\sqrt{x}} \frac{(\pi)x^{-x/\sqrt{2}}}{2x} e^{-x/\sqrt{2}}$ , becomes so

small that it cannot be calculated without causing underflow, and the routine returns zero. Note that for large  $x$  the errors are dominated by those of the Fortran intrinsic function EXP.

## 8. Further Comments

Underflow may occur for a few values of  $x$  close to the zeros of  $\ker x$ , below the limit which causes a failure with  $IFAIL = 1$ .

## 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S19 -- Approximations of Special Functions S19ADF  
 S19ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

S19ADF returns a value for the Kelvin function  $keix$  via the routine name.

## 2. Specification

```
DOUBLE PRECISION FUNCTION S19ADF (X, IFAIL)
      INTEGER      IFAIL
      DOUBLE PRECISION X
```

## 3. Description

This routine evaluates an approximation to the Kelvin function  $keix$ .

Note: for  $x < 0$  the function is undefined, so we need only consider  $x \geq 0$ .

The routine is based on several Chebyshev expansions:

For  $0 \leq x \leq 1$ ,

$$(\pi) \quad x^2$$

$$keix = - \frac{f(t)}{4} + \frac{1}{4} [-g(t) \log x + v(t)]$$

where  $f(t)$ ,  $g(t)$  and  $v(t)$  are expansions in the variable  $t = 2x^{-1/2}$ ;

For  $1 < x \leq 3$ ,

$$keix = \exp\left(-\frac{x}{8}\right) u(t)$$

where  $u(t)$  is an expansion in the variable  $t = x - 2$ ;

For  $x > 3$ ,

$$keix = \frac{1}{\sqrt{2x}} \frac{(\pi)^{-x/\sqrt{2}}}{e^{-(1-x)c(t)\sin(\beta) - d(t)\cos(\beta)}}$$

where  $(\beta) = \frac{x(\pi)}{8}$ , and  $c(t)$  and  $d(t)$  are expansions in the

variable  $t = \frac{\sqrt{2}}{6} - \frac{1}{x}$ .

For  $x < 0$ , the function is undefined, and hence the routine fails and returns zero.

When  $x$  is sufficiently close to zero, the result is computed as

$$keix = - \frac{(\pi)^{(x)} (x)^2}{4} + (1 - \gamma) - \log\left(\frac{(x)}{(2)}\right) - \frac{1}{4}$$

and when  $x$  is even closer to zero simply as

$$keix = - \frac{(\pi)}{4}$$

$$\frac{1}{\sqrt{2x}} (\pi)^{-x/\sqrt{2}}$$

For large  $x$ ,  $\text{keix}$  is asymptotically given by  $\frac{1}{\sqrt{2x}} e^{-x}$  and

this becomes so small that it cannot be computed without underflow and the routine fails.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

1: X -- DOUBLE PRECISION Input  
 On entry: the argument  $x$  of the function. Constraint:  $X \geq 0$ .

2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 On entry  $X$  is too large, the result underflows. On soft failure, the routine returns zero.

IFAIL= 2  
 On entry  $X < 0$ , the function is undefined. On soft failure the routine returns zero.

#### 7. Accuracy

Let  $E$  be the absolute error in the result, and  $(\delta)$  be the relative error in the argument. If  $(\delta)$  is somewhat larger than the machine representation error, then we have:

$$E \sim \frac{x}{\sqrt{2}} \left( -\text{ker} \frac{x}{1} + \text{kei} \frac{x}{1} \right) (\delta).$$

For small  $x$ , errors are attenuated by the function and hence are limited by the machine precision.

For medium and large  $x$ , the error behaviour, like the function itself, is oscillatory and hence only absolute accuracy of the function can be maintained. For this range of  $x$ , the amplitude of

the absolute error decays like  $\frac{1}{\sqrt{x}} \frac{(\pi)x^{-x/\sqrt{2}}}{2}$ , which implies a

strong attenuation of error. Eventually,  $\text{keix}$ , which is

asymptotically given by  $\frac{1}{\sqrt{x}} \frac{(\pi)x^{-x/\sqrt{2}}}{2x}$ , becomes so small that it

cannot be calculated without causing underflow and therefore the routine returns zero. Note that for large  $x$ , the errors are dominated by those of the Fortran intrinsic function EXP.

## 8. Further Comments

Underflow may occur for a few values of  $x$  close to the zeros of  $\text{keix}$ , below the limit which causes a failure with IFAIL = 1.

## 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S20 -- Approximations of Special Functions S20ACF  
S20ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

S20ACF returns a value for the Fresnel Integral  $S(x)$ , via the routine name.

## 2. Specification

```

DOUBLE PRECISION FUNCTION S20ACF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X

```

## 3. Description

This routine evaluates an approximation to the Fresnel Integral

$$S(x) = \frac{x}{\sqrt{\pi}} \int_0^{\sqrt{\pi} x} \sin(t^2) dt.$$

Note:  $S(x) = -S(-x)$ , so the approximation need only consider  $x \geq 0.0$

The routine is based on three Chebyshev expansions:

For  $0 < x \leq 3$ ,

$$S(x) = x \sum_{r=0}^3 a_r T_r(t), \text{ with } t = 2\left(\frac{x}{3}\right)^4 - 1;$$

For  $x > 3$ ,

$$S(x) = \frac{1}{2} \frac{f(x)}{x} \cos\left(\frac{\pi}{2} x\right) - \frac{g(x)}{3x} \sin\left(\frac{\pi}{2} x\right),$$

$$\text{where } f(x) = \sum_{r=0}^3 b_r T_r(t),$$

$$\text{and } g(x) = \sum_{r=0}^3 c_r T_r(t), \text{ with } t = 2\left(\frac{x}{3}\right)^4 - 1.$$

For small  $x$ ,  $S(x) \sim \frac{\pi}{6} x^3$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision. For very small  $x$ , this approximation would underflow; the result is then set exactly to zero.

For large  $x$ ,  $f(x) \sim \frac{1}{(\pi)^2}$  and  $g(x) \sim \frac{1}{(\pi)^2}$ . Therefore for moderately large  $x$ , when  $\frac{1}{(\pi)^2 x^3}$  is negligible compared with  $\frac{1}{2}$ , the second term in the approximation for  $x > 3$  may be dropped. For very large  $x$ , when  $\frac{1}{(\pi)x}$  becomes negligible,  $S(x) \sim \frac{1}{2}$ . However there will be considerable difficulties in calculating  $\cos\left(\frac{(\pi)^2}{2}x\right)$  accurately before this final limiting value can be used. Since  $\cos\left(\frac{(\pi)^2}{2}x\right)$  is periodic, its value is essentially determined by the fractional part of  $x$ . If  $x = N + (\theta)$  where  $N$  is an integer and  $0 \leq (\theta) < 1$ , then  $\cos\left(\frac{(\pi)^2}{2}x\right)$  depends on  $(\theta)$  and on  $N$  modulo 4. By exploiting this fact, it is possible to retain significance in the calculation of  $\cos\left(\frac{(\pi)^2}{2}x\right)$  either all the way to the very large  $x$  limit, or at least until the integer part of  $\frac{x}{2}$  is equal to the maximum integer allowed on the machine.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
On entry: the argument  $x$  of the function.
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL has been included for consistency with other routines in this chapter.

## 7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

$$(\epsilon) \sim \frac{(\pi)^2 |x \sin(\frac{x}{2})|}{|S(x)|} (\delta).$$

Figure 1 shows the behaviour of the error amplification factor

$$\frac{(\pi)^2 |x \sin(\frac{x}{2})|}{|S(x)|}.$$

Figure 1

Please see figure in printed Reference Manual

However if (delta) is of the same order as the machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

For small x, (epsilon)~3(delta) and hence there is only moderate amplification of relative error. Of course for very small x where the correct result would underflow and exact zero is returned, relative error-control is lost.

For moderately large values of x,

$$(\epsilon) \sim 2|x \sin(\frac{x}{2})| (\delta).$$

and the result will be subject to increasingly large amplification of errors. However the above relation breaks down

$$\frac{1}{2}x^2$$

for large values of  $x$  (i.e., when  $\frac{1}{2}x^2$  is of the order of the machine precision in this region the relative error in the result is essentially bounded by  $\frac{1}{2}(\pi)x$ ).

Hence the effects of error amplification are limited and at worst the relative error loss should not exceed half the possible number of significant figures.

#### 8. Further Comments

None.

#### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S20 -- Approximations of Special Functions S20ADF  
S20ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S20ADF returns a value for the Fresnel Integral  $C(x)$ , via the routine name.

#### 2. Specification

```
DOUBLE PRECISION FUNCTION S20ADF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

## 3. Description

This routine evaluates an approximation to the Fresnel Integral

$$C(x) = \frac{1}{\sqrt{\pi}} \int_0^x \cos\left(\frac{t^2}{2}\right) dt.$$

Note:  $C(x) = -C(-x)$ , so the approximation need only consider  $x \geq 0.0$

The routine is based on three Chebyshev expansions:

For  $0 \leq x \leq 3$ ,

$$C(x) = x + \sum_{r=1}^4 a_r T_r(t), \text{ with } t = 2\left(\frac{x}{3}\right)^3 - 1;$$

For  $x > 3$ ,

$$C(x) = \frac{1}{2} \frac{f(x)}{x} + \frac{(\pi/2)}{x^2} \sin\left(\frac{g(x)}{x}\right) - \frac{(\pi/2)}{3x^3} \cos\left(\frac{g(x)}{x}\right),$$

$$\text{where } f(x) = \sum_{r=1}^4 b_r T_r(t),$$

$$\text{and } g(x) = \sum_{r=1}^4 c_r T_r(t), \text{ with } t = 2\left(\frac{x}{3}\right)^3 - 1.$$

For small  $x$ ,  $C(x) \sim x$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision.

$$\text{For large } x, f(x) \sim \frac{1}{(\pi)} \text{ and } g(x) \sim \frac{1}{2(\pi)}.$$

$$\text{moderately large } x, \text{ when } \frac{1}{2(\pi)x^3} \text{ is negligible compared with } \frac{1}{2(\pi)x^2},$$

the second term in the approximation for  $x > 3$  may be dropped. For

very large  $x$ , when  $\frac{1}{(\pi)x}$  becomes negligible,  $C(x) \sim -\frac{1}{2}$ . However there will be considerable difficulties in calculating  $\sin\left(\frac{(\pi)x^2}{2}\right)$  accurately before this final limiting value can be

used. Since  $\sin\left(\frac{(\pi)x^2}{2}\right)$  is periodic, its value is essentially

determined by the fractional part of  $x^2$ . If  $x^2 = N + (\theta)$ , where  $N$  is an integer and  $0 \leq (\theta) < 1$ , then  $\sin\left(\frac{(\pi)x^2}{2}\right)$  depends on

$(\theta)$  and on  $N$  modulo 4. By exploiting this fact, it is possible to retain some significance in the calculation of  $\sin\left(\frac{(\pi)x^2}{2}\right)$  either all the way to the very large  $x$  limit, or at

least until the integer part of  $\frac{x^2}{2}$  is equal to the maximum integer allowed on the machine.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

1: X -- DOUBLE PRECISION Input  
On entry: the argument  $x$  of the function.

2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL has been included for consistency with other routines in this chapter.

## 7. Accuracy

Let  $(\delta)$  and  $(\epsilon)$  be the relative errors in the argument and result respectively.

If  $(\delta)$  is somewhat larger than the machine precision (i.e. if  $(\delta)$  is due to data errors etc), then  $(\epsilon)$  and  $(\delta)$  are approximately related by:

$$(\epsilon) \sim \frac{(\pi)^2}{2 C(x)} (\delta).$$

Figure 1 shows the behaviour of the error amplification factor

$$\frac{(\pi)^2}{2 C(x)}.$$

Figure 1

Please see figure in printed Reference Manual

However if  $(\delta)$  is of the same order as the machine precision, then rounding errors could make  $(\epsilon)$  slightly larger than the above relation predicts.

For small  $x$ ,  $(\epsilon) \sim (\delta)$  and there is no amplification of relative error.

For moderately large values of  $x$ ,

$$(\epsilon) \sim 2 \frac{(\pi)^2}{C(x)} (\delta)$$

and the result will be subject to increasingly large amplification of errors. However the above relation breaks down

for large values of  $x$  (i.e., when  $\frac{1}{2}$  is of the order of the machine precision); in this region the relative error in the result is essentially bounded by  $\frac{x}{(\pi)x}$ .

Hence the effects of error amplification are limited and at worst the relative error loss should not exceed half the possible number of significant figures.

#### 8. Further Comments

None.

#### 9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S21 -- Approximations of Special Functions S21BAF  
 S21BAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S21BAF returns a value of an elementary integral, which occurs as a degenerate case of an elliptic integral of the first kind, via the routine name.

#### 2. Specification

```
DOUBLE PRECISION FUNCTION S21BAF (X, Y, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X, Y
```

#### 3. Description

This routine calculates an approximate value for the integral

$$R(x,y) = \frac{1}{C} \int_0^{\infty} \frac{dt}{\sqrt{t^2 + x(t+y)}}$$

where  $x \geq 0$  and  $y \neq 0$ .

This function, which is related to the logarithm or inverse hyperbolic functions for  $y < x$  and to inverse circular functions if  $x < y$ , arises as a degenerate form of the elliptic integral of the first kind. If  $y < 0$ , the result computed is the Cauchy principal value of the integral.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the system:

$$\begin{aligned} x_n &= x, \\ 0 \\ y_n &= y \\ 0 \\ (\mu)_n &= (x_n + 2y_n)/3, \\ S_n &= (y_n - x_n)/3(\mu)_n \\ (\lambda)_n &= y_n + 2\sqrt{x_n y_n} \\ x_{n+1} &= (x_n + (\lambda)_n)/4, \\ y_{n+1} &= (y_n + (\lambda)_n)/4. \end{aligned}$$

The quantity  $|S_n|$  for  $n=0,1,2,3,\dots$  decreases with increasing  $n$ ,

eventually  $|S_n| \sim 1/4^n$ . For small enough  $S_n$  the required function value can be approximated by the first few terms of the Taylor series about the mean. That is

$$R(x,y) = \frac{1}{C} \left( 1 + \frac{3S_n^2}{10} + \frac{S_n^3}{7} + \frac{3S_n^4}{8} + \frac{9S_n^5}{22} \right) \sqrt{(\mu)_n}.$$

The truncation error involved in using this approximation is

$$\frac{6}{n} \frac{|S|}{(1-2|S|)^n}$$
 bounded by  $\frac{6}{n} \frac{|S|}{(1-2|S|)^n}$  and the recursive process is stopped when  $S$  is small enough for this truncation error to be negligible compared to the machine precision.

Within the domain of definition, the function value is itself representable for all representable values of its arguments. However, for values of the arguments near the extremes the above algorithm must be modified so as to avoid causing underflows or overflows in intermediate steps. In extreme regions arguments are pre-scaled away from the extremes and compensating scaling of the result is done before returning to the calling program.

- [3] Carlson B C (1988) A Table of Elliptic Integrals of the Third Kind. Math. Comput. 51 267--280.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input
- 2: Y -- DOUBLE PRECISION Input  
 On entry: the arguments x and y of the function, respectively. Constraint: X >= 0.0 and Y /= 0.0.
- 3: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry  $X < 0.0$ ; the function is undefined.

IFAIL= 2

On entry  $Y = 0.0$ ; the function is undefined.

On soft failure the routine returns zero.

#### 7. Accuracy

In principle the routine is capable of producing full machine precision. However round-off errors in internal arithmetic will result in slight loss of accuracy. This loss should never be excessive as the algorithm does not involve any significant amplification of round-off error. It is reasonable to assume that the result is accurate to within a small multiple of the machine precision.

#### 8. Further Comments

Users should consult the Chapter Introduction which shows the relationship of this function to the classical definitions of the elliptic integrals.

#### 9. Example

This example program simply generates a small set of non-extreme arguments which are used with the routine to produce the table of low accuracy results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S21 -- Approximations of Special Functions S21BBF  
 S21BBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S21BBF returns a value of the symmetrised elliptic integral of the first kind, via the routine name.

#### 2. Specification

```

DOUBLE PRECISION FUNCTION S21BBF (X, Y, Z, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X, Y, Z

```

### 3. Description

This routine calculates an approximation to the integral

$$R(x,y,z) = - \int_0^{\infty} \frac{dt}{2 \sqrt{(t+x)(t+y)(t+z)}}$$

where  $x, y, z \geq 0$  and at most one is zero.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the rule:

$$x = \min(x, y, z), z = \max(x, y, z),$$

$$0 \qquad \qquad \qquad 0$$

$$y = \text{remaining third intermediate value argument.}$$

$$0$$

(This ordering, which is possible because of the symmetry of the function, is done for technical reasons related to the avoidance of overflow and underflow.)

$$(\mu)_n = (x_n + y_n + 3z_n)/3$$

$$X_n = (1 - x_n)/(\mu)_n$$

$$Y_n = (1 - y_n)/(\mu)_n$$

$$Z_n = (1 - z_n)/(\mu)_n$$

$$(\lambda)_{n+1} = \sqrt{x_n y_n} + \sqrt{y_n z_n} + \sqrt{z_n x_n}$$

$$x_{n+1} = (x_n + (\lambda)_{n+1})/4$$

$$y_{n+1} = (y_n + (\lambda)_n) / 4$$

$$z_{n+1} = (z_n + (\lambda)_n) / 4$$

$(\epsilon) = \max(|X_n|, |Y_n|, |Z_n|)$  and the function may be approximated adequately by a 5th order power series:

$$R_F(x, y, z) = \frac{1}{\sqrt{\mu}} \frac{\left( \begin{matrix} 2 \\ E^2 E^2 3E^2 E^2 \end{matrix} \right)}{\left( \begin{matrix} 2 & 2 & 2 & 3 & 3 \\ 10 & 24 & 44 & 14 \end{matrix} \right)} (1 - \frac{\mu}{10} + \frac{\mu^2}{24} - \frac{\mu^3}{44} + \frac{\mu^4}{14})$$

where  $E^2 = X^2 Y^2 + Y^2 Z^2 + Z^2 X^2$ ,  $E^3 = X^3 Y^2 Z^2$ .

The truncation error involved in using this approximation is bounded by  $(\epsilon)^6 / 4(1 - (\epsilon))$  and the recursive process is stopped when this truncation error is negligible compared with the machine precision.

Within the domain of definition, the function value is itself representable for all representable values of its arguments. However, for values of the arguments near the extremes the above algorithm must be modified so as to avoid causing underflows or overflows in intermediate steps. In extreme regions arguments are pre-scaled away from the extremes and compensating scaling of the result is done before returning to the calling program.

#### 5. Parameters

1: X -- DOUBLE PRECISION Input  
2: Y -- DOUBLE PRECISION Input  
3: Z -- DOUBLE PRECISION Input  
On entry: the arguments x, y and z of the function.  
Constraint: X, Y, Z  $\geq 0.0$  and only one of X, Y and Z may be zero.  
4: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry one or more of X, Y and Z is negative; the function is undefined.

IFAIL= 2

On entry two or more of X, Y and Z are zero; the function is undefined.

On soft failure, the routine returns zero.

#### 7. Accuracy

In principle the routine is capable of producing full machine precision. However round-off errors in internal arithmetic will result in slight loss of accuracy. This loss should never be excessive as the algorithm does not involve any significant amplification of round-off error. It is reasonable to assume that the result is accurate to within a small multiple of the machine precision.

#### 8. Further Comments

Users should consult the Chapter Introduction which shows the relationship of this function to the classical definitions of the elliptic integrals.

If two arguments are equal, the function reduces to the elementary integral  $R$ , computed by S21BAF.

C

### 9. Example

This example program simply generates a small set of non-extreme arguments which are used with the routine to produce the table of low accuracy results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S21 -- Approximations of Special Functions S21BCF  
 S21BCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S21BCF returns a value of the symmetrised elliptic integral of the second kind, via the routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S21BCF (X, Y, Z, IFAIL)
  INTEGER          IFAIL
  DOUBLE PRECISION X, Y, Z
```

### 3. Description

This routine calculates an approximate value for the integral

$$R(x,y,z) = \frac{3}{2} \int_0^{\infty} \frac{dt}{\sqrt{(t+x)(t+y)(t+z)}}$$

where  $x, y \geq 0$ , at most one of  $x$  and  $y$  is zero, and  $z > 0$ .

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the rule:

$$x_0 = x$$

$$y_0 = y$$

$$z_0 = z$$

$$(\mu)_n = (x_n + y_n + 3z_n)/5$$

$$X_n = (1 - x_n)/(\mu)_n$$

$$Y_n = (1 - y_n)/(\mu)_n$$

$$Z_n = (1 - z_n)/(\mu)_n$$

$$(\lambda)_n = \sqrt[n]{x_n y_n + y_n z_n + z_n x_n}$$

$$x_{n+1} = (x_n + (\lambda)_n)/4$$

$$y_{n+1} = (y_n + (\lambda)_n)/4$$

$$z_{n+1} = (z_n + (\lambda)_n)/4$$

For  $n$  sufficiently large,

$$(\epsilon)_n = \max(|X_n|, |Y_n|, |Z_n|)^{(1/n)}$$

and the function may be approximated adequately by a 5th order

$$\text{power series } R(x, y, z) = \sum_{m=0}^{\infty} \frac{(z_n + (\lambda)_n)^{-m}}{n \sqrt[n]{m}}$$

$$\begin{aligned}
& \frac{1}{n} \left[ \begin{array}{c} 3 \quad (2) \quad 1 \quad (3) \quad 3 \quad (2) \quad 2 \quad 3 \quad (4) \quad 3 \quad (2) \quad (3) \quad 3 \quad (5) \\ 1 + -S + -S + --(S) + --S + --S S + --S \\ 7 n \quad 3 n \quad 22 n \quad 11 n \quad 13 n \quad n \quad 13 n \end{array} \right] \\
& \quad / \quad 3 \\
& \quad / \quad (\mu) \\
& \quad \backslash \quad n
\end{aligned}$$

where

$$\begin{aligned}
& S_{(m)}^{(m)} = (X + Y + 3Z) / 2m. \\
& \quad \quad \quad n \quad (n \quad n \quad n)
\end{aligned}$$

The truncation error in this expansion is bounded by

$$\begin{aligned}
& \frac{3(\epsilon)}{n^6} \\
& \text{-----} \text{ and the recursive process is terminated when}
\end{aligned}$$

$$\begin{aligned}
& \quad / \quad 3 \\
& \quad / \quad (1 - (\epsilon)) \\
& \quad \backslash \quad n
\end{aligned}$$

this quantity is negligible compared with the machine precision.

The routine may fail either because it has been called with arguments outside the domain of definition, or with arguments so extreme that there is an unavoidable danger of setting underflow or overflow.

Note:  $R(x, x, x) = x^{-3/2}$ , so there exists a region of extreme arguments for which the function value is not representable.

#### 5. Parameters

1: X -- DOUBLE PRECISION Input

2: Y -- DOUBLE PRECISION Input

3: Z -- DOUBLE PRECISION Input  
 On entry: the arguments x, y and z of the function.  
 Constraint: X, Y  $\geq$  0.0, Z > 0.0 and only one of X and Y may be zero.

4: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry either X or Y is negative, or both X and Y are zero; the function is undefined.

IFAIL= 2

On entry Z  $\leq$  0.0; the function is undefined.

IFAIL= 3

On entry either Z is too close to zero or both X and Y are too close to zero: there is a danger of setting overflow.

IFAIL= 4

On entry at least one of X, Y and Z is too large: there is a danger of setting underflow.

On soft failure the routine returns zero.

#### 7. Accuracy

In principle the routine is capable of producing full machine precision. However round-off errors in internal arithmetic will result in slight loss of accuracy. This loss should never be excessive as the algorithm does not involve any significant amplification of round-off error. It is reasonable to assume that the result is accurate to within a small multiple of the machine

precision.

#### 8. Further Comments

Users should consult the Chapter Introduction which shows the relationship of this function to the classical definitions of the elliptic integrals.

#### 9. Example

This example program simply generates a small set of non-extreme arguments which are used with the routine to produce the table of low accuracy results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S21 -- Approximations of Special Functions S21BDF  
 S21BDF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S21BDF returns a value of the symmetrised elliptic integral of the third kind, via the routine name.

#### 2. Specification

```
DOUBLE PRECISION FUNCTION S21BDF (X, Y, Z, R, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X, Y, Z, R
```

#### 3. Description

This routine calculates an approximation to the integral

$$R(x, y, z, (\rho)) = \int_0^{\infty} \frac{dt}{(t + (\rho)) \sqrt{(t + x)(t + y)(t + z)}}$$

where  $x, y, z \geq 0$ ,  $(\rho) \neq 0$  and at most one of  $x, y$  and  $z$  is zero.

If  $p < 0$ , the result computed is the Cauchy principal value of the integral.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the rule:

$$x_0 = x$$

$$y_0 = y$$

$$z_0 = z$$

$$(\rho)_0 = (\rho)$$

$$(\mu)_n = (x_n + y_n + z_n + 2(\rho)_n) / 5$$

$$X_n = (1 - x_n) / (\mu)_n$$

$$Y_n = (1 - y_n) / (\mu)_n$$

$$Z_n = (1 - z_n) / (\mu)_n$$

$$P_n = (1 - (\rho)_n) / (\mu)_n$$

$$(\lambda)_n = \sqrt{x_n y_n + y_n z_n + z_n x_n}$$

$$x_{n+1} = (x_n + (\lambda)_n) / 4$$

$$y_{n+1} = (y_n + (\lambda)_n) / 4$$

$$z_{n+1} = (z_n + (\lambda)_n) / 4$$

$$(\rho)_{n+1} = ((\rho)_n + (\lambda)_n) / 4$$

$$(\alpha) = \left[ \frac{(\rho)}{n} \left( \frac{1}{n} \sqrt{\frac{x}{n} + \frac{y}{n} + \frac{z}{n}} \right) + \frac{xyz}{n^3} \right]^2$$

$$(\beta) = \frac{(\rho)}{n} \left( \frac{(\rho)}{n} + \frac{(\lambda)}{n} \right)^2$$

For  $n$  sufficiently large,

$$(\epsilon) = \max \left( |X|, |Y|, |Z|, |P| \right)^{\frac{1}{4}} \sim \frac{1}{n}$$

and the function may be approximated by a 5th order power series

$$R(x, y, z, (\rho)) = \sum_{m=0}^{n-1} \frac{1}{C_m} R((\alpha), (\beta))$$

$$+ \frac{1}{\sqrt{\mu}} \left[ \frac{1}{7n} S^{(2)} + \frac{1}{3n} S^{(3)} + \frac{1}{22n} S^{(4)} + \frac{1}{11n} S^{(5)} + \frac{1}{13n} S^{(6)} + \frac{1}{13n} S^{(7)} \right]$$

where  $S^{(m)} = (X^m + Y^m + Z^m + 2P^m) / 2m$ .

The truncation error in this expansion is bounded by

$$3(\epsilon)^{\frac{6}{n}} / (1 - (\epsilon)^{\frac{3}{n}})$$

and the recursion process is terminated when this quantity is negligible compared with the machine precision. The routine may fail either because it has been called with arguments outside the domain of definition or with arguments so extreme that there is an unavoidable danger of setting underflow or overflow.

## 2

Note:  $R(x, x, x, x) = x^J$ , so there exists a region of extreme arguments for which the function value is not representable.

## 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.
- [2] Carlson B C (1978) Computing Elliptic Integrals by Duplication. (Preprint) Department of Physics, Iowa State University.
- [3] Carlson B C (1988) A Table of Elliptic Integrals of the Third Kind. Math. Comput. 51 267--280.

## 5. Parameters

- 1: X -- DOUBLE PRECISION Input
- 2: Y -- DOUBLE PRECISION Input
- 3: Z -- DOUBLE PRECISION Input
- 4: R -- DOUBLE PRECISION Input  
 On entry: the arguments x, y, z and (rho) of the function.  
 Constraint: X, Y, Z  $\geq$  0.0, R  $\neq$  0.0 and at most one of X, Y and Z may be zero.
- 5: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry at least one of X, Y and Z is negative, or at least two of them are zero; the function is undefined.

IFAIL= 2

On entry R = 0.0; the function is undefined.

IFAIL= 3

On entry either R is too close to zero, or any two of X, Y and Z are too close to zero; there is a danger of setting overflow.

IFAIL= 4

On entry at least one of X, Y, Z and R is too large; there is a danger of setting underflow.

IFAIL= 5

An error has occurred in a call to S21BAF. Any such occurrence should be reported to NAG.

On soft failure, the routine returns zero.

#### 7. Accuracy

In principle the routine is capable of producing full machine precision. However round-off errors in internal arithmetic will result in slight loss of accuracy. This loss should never be excessive as the algorithm does not involve any significant amplification of round-off error. It is reasonable to assume that the result is accurate to within a small multiple of the machine precision.

#### 8. Further Comments

Users should consult the Chapter Introduction which shows the relationship of this function to the classical definitions of the elliptic integrals.

If the argument R is equal to any of the other arguments, the function reduces to the integral  $\int_0^R \frac{1}{\sqrt{1-t^2}} dt$ , computed by S21BCF.

D

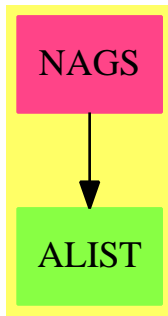

#### 9. Example

This example program simply generates a small set of non-extreme arguments which are used with the routine to produce the table of low accuracy results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

++ See \downlink{Manual Page}{manpageXXs18adf}.
s18aef : (DoubleFloat,Integer) -> Result
++ s18aef(x,ifail)
++ returns the value of the modified Bessel Function
++ I (x), via the routine name.
++ 0
++ See \downlink{Manual Page}{manpageXXs18aef}.
s18aff : (DoubleFloat,Integer) -> Result
++ s18aff(x,ifail)
++ returns a value for the modified Bessel Function
++ I (x), via the routine name.
++ 1
++ See \downlink{Manual Page}{manpageXXs18aff}.
s18dcf : (DoubleFloat,Complex DoubleFloat,Integer,String,_
Integer) -> Result
++ s18dcf(fnu,z,n,scale,ifail)
++ returns a sequence of values for the modified Bessel functions
++ K (z) for complex z, non-negative (nu) and
++ (nu)+n
++ n=0,1,...,N-1, with an option for exponential scaling.
++ See \downlink{Manual Page}{manpageXXs18dcf}.
s18def : (DoubleFloat,Complex DoubleFloat,Integer,String,_
Integer) -> Result
++ s18def(fnu,z,n,scale,ifail)

```

```

++ returns a sequence of values for the modified Bessel functions
++  $I_{\nu}(z)$  for complex  $z$ , non-negative  $(\nu)$  and
++  $(\nu)+n$ 
++  $n=0,1,\dots,N-1$ , with an option for exponential scaling.
++ See \downlink{Manual Page}{manpageXXs18def}.
s19aaf : (DoubleFloat,Integer) -> Result
++ s19aaf(x,ifail)
++ returns a value for the Kelvin function ber(x) via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs19aaf}.
s19abf : (DoubleFloat,Integer) -> Result
++ s19abf(x,ifail)
++ returns a value for the Kelvin function bei(x) via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs19abf}.
s19acf : (DoubleFloat,Integer) -> Result
++ s19acf(x,ifail)
++ returns a value for the Kelvin function ker(x), via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs19acf}.
s19adf : (DoubleFloat,Integer) -> Result
++ s19adf(x,ifail)
++ returns a value for the Kelvin function kei(x) via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs19adf}.
s20acf : (DoubleFloat,Integer) -> Result
++ s20acf(x,ifail)
++ returns a value for the Fresnel Integral  $S(x)$ , via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs20acf}.
s20adf : (DoubleFloat,Integer) -> Result
++ s20adf(x,ifail)
++ returns a value for the Fresnel Integral  $C(x)$ , via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs20adf}.
s21baf : (DoubleFloat,DoubleFloat,Integer) -> Result
++ s21baf(x,y,ifail)
++ returns a value of an elementary integral, which occurs as
++ a degenerate case of an elliptic integral of the first kind, via
++ the routine name.
++ See \downlink{Manual Page}{manpageXXs21baf}.
s21bbf : (DoubleFloat,DoubleFloat,DoubleFloat,Integer) -> Result
++ s21bbf(x,y,z,ifail)
++ returns a value of the symmetrised elliptic integral of
++ the first kind, via the routine name.
++ See \downlink{Manual Page}{manpageXXs21bbf}.
s21bcf : (DoubleFloat,DoubleFloat,DoubleFloat,Integer) -> Result
++ s21bcf(x,y,z,ifail)
++ returns a value of the symmetrised elliptic integral of
++ the second kind, via the routine name.

```

```

++ See \downlink{Manual Page}{manpageXXs21bcf}.
s21bdf : (DoubleFloat,DoubleFloat,DoubleFloat,DoubleFloat,_
Integer) -> Result
++ s21bdf(x,y,z,r,ifail)
++ returns a value of the symmetrised elliptic integral of
++ the third kind, via the routine name.
++ See \downlink{Manual Page}{manpageXXs21bdf}.

)abbrev package NUMFMT NumberFormats
++ SMW March 88
++ Description:
++ NumberFormats provides function to format and read arabic and
++ roman numbers, to convert numbers to strings and to read
++ floating-point numbers.

NumberFormats(): NFexports == NFimplementation where
  PI ==> PositiveInteger
  I  ==> Integer
  C  ==> Character
  F  ==> Float
  S  ==> String
  V  ==> PrimitiveArray

  NFexports ==> with
    FormatArabic: PI -> S
      ++ FormatArabic(n) forms an Arabic numeral
      ++ string from an integer n.
    ScanArabic:  S -> PI
      ++ ScanArabic(s) forms an integer from an Arabic numeral string s.
    FormatRoman: PI -> S
```

```

    ++ FormatRoman(n) forms a Roman numeral string from an integer n.
ScanRoman:    S -> PI
    ++ ScanRoman(s) forms an integer from a Roman numeral string s.
ScanFloatIgnoreSpaces: S -> F
    ++ ScanFloatIgnoreSpaces(s) forms a floating point number from
    ++ the string s ignoring any spaces. Error is generated if the
    ++ string is not recognised as a floating point number.
ScanFloatIgnoreSpacesIfCan: S -> Union(F, "failed")
    ++ ScanFloatIgnoreSpacesIfCan(s) tries to form a floating point
    ++ number from the string s ignoring any spaces.

NumericalOrdinaryDifferentialEquations examples
=====
```

This package is a suite of functions for the numerical integration of an ordinary differential equation of  $n$  variables:

$$dy/dx = f(y,x) \quad y \text{ is an } n\text{-vector}$$

All the routines are based on a 4-th order Runge-Kutta kernel.

These routines generally have as arguments:

```

n,      the number of dependent variables;\br
x1,     the initial point;\br
h,      the step size;\br
y,      a vector of initial conditions of length n\br

```

which upon exit contains the solution at  $x1 + h$

derivs, a function which computes the right hand side of the ordinary differential equation:

```
derivs(dydx,y,x)
```

computes dydx, a vector which contains the derivative information.

In order of increasing complexity:

```
rk4(y,n,x1,h,derivs)
```

advances the solution vector to

```
x1 + h
```

and return the values in y.

```
rk4(y,n,x1,h,derivs,t1,t2,t3,t4)
```

is the same as

```
rk4(y,n,x1,h,derivs)
```

except that you must provide 4 scratch

```
arrays t1-t4 of size n
```

Starting with y at x1,

```
rk4f(y,n,x1,x2,ns,derivs)
```

uses ns fixed steps of a 4-th order Runge-Kutta integrator to advance the solution vector to x2 and return the values in y. Argument x2, is the final point, and ns, the number of steps to take.

```
rk4qc(y,n,x1,step,eps,yscal,derivs)
```

takes a 5-th order Runge-Kutta step with monitoring of local truncation to ensure accuracy and adjust stepsize.

The function takes two half steps and one full step and scales the difference in solutions at the final point. If the error is

within eps, the step is taken and the result is returned.

If the error is not within eps, the stepsize is decreased and the procedure is tried again until the desired accuracy is reached. Upon input, a trial step size must be given and upon return, an estimate of the next step size to use is returned as well as the step size which produced the desired accuracy.

The scaled error is computed as

```
error = MAX(ABS((y2steps(i) - y1step(i))/yscal(i)))
```

and this is compared against eps. If this is greater than eps, the step size is reduced accordingly to

```
hnew = 0.9 * hdid * (error/eps)**(-1/4)
```

If the error criterion is satisfied, then we check if the step size was too fine and return a more efficient one. If

```
error > eps * (6.0E-04)
```

then the next step size should be

```
hnext = 0.9 * hdid * (error/eps)**(-1/5)
```

Otherwise

```
hnext = 4.0 * hdid
```

is returned.

A more detailed discussion of this and related topics can be found in the book "Numerical Recipes" by W.Press, B.P. Flannery, S.A. Teukolsky, W.T. Vetterling published by Cambridge University Press.

Argument step is a record of 3 floating point numbers (try, did, next), eps is the required accuracy, yscal is the scaling vector for the difference in solutions.

On input, step.try should be the guess at a step size to achieve the accuracy. On output, step.did contains the step size which achieved the accuracy and step.next is the next step size to use.

```
rk4qc(y,n,x1,step,eps,yscal,derivs,t1,t2,t3,t4,t5,t6,t7)
```

is the same as

```
rk4qc(y,n,x1,step,eps,yscal,derivs)
```

except that the user must provide the 7 scratch arrays t1-t7 of size n.

```
rk4a(y,n,x1,x2,eps,h,ns,derivs)
```

is a driver program which uses rk4qc to integrate n ordinary differential equations starting at x1 to x2, keeping the local truncation error to within eps by changing the local step size.

The scaling vector is defined as

```
yscal(i) = abs(y(i)) + abs(h*dydx(i)) + tiny
```

where y(i) is the solution at location x, dydx is the ordinary differential equation's right hand side, h is the current step size and tiny is 10 times the smallest positive number representable.

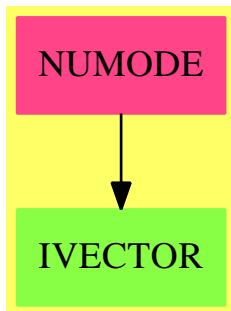

The user must supply an estimate for a trial step size and the maximum number of calls to rk4qc to use. Argument x2 is the final point, eps is local truncation, ns is the maximum number of call to rk4qc to use.

++ Author: Yuriy Baransky
++ Date Created: October 90
++ Date Last Updated: October 90
++ Description:
++ This package is a suite of functions for the numerical integration of an
++ ordinary differential equation of n variables:\br
++ \tab{5}dy/dx = f(y,x)\tab{5}y is an n-vector\br
++ All the routines are based on a 4-th order Runge-Kutta kernel.
++ These routines generally have as arguments:\br
++ n, the number of dependent variables;\br
++ x1, the initial point;\br
++ h, the step size;\br
++ y, a vector of initial conditions of length n\br
++ which upon exit contains the solution at \spad{x1 + h};\br
++
++ \spad{derivs}, a function which computes the right hand side of the
++ ordinary differential equation: \spad{derivs(dydx,y,x)} computes
++ \spad{dydx}, a vector which contains the derivative information.
++
++ In order of increasing complexity:\br
++ \tab{5}\spad{rk4(y,n,x1,h,derivs)} advances the solution vector to\br
++ \tab{5}\spad{x1 + h} and return the values in y.\br
++
++ \tab{5}\spad{rk4(y,n,x1,h,derivs,t1,t2,t3,t4)} is the same as\br
++ \tab{5}\spad{rk4(y,n,x1,h,derivs)} except that you must provide 4 scratch\br
++ \tab{5}arrays t1-t4 of size n.\br
++
++ \tab{5}Starting with y at x1, \spad{rk4f(y,n,x1,x2,ns,derivs)}\br
++ \tab{5}uses \spad{ns} fixed steps of a 4-th order Runge-Kutta\br
++ \tab{5}integrator to advance the solution vector to x2 and return\br
++ \tab{5}the values in y. Argument x2, is the final point, and\br
++ \tab{5}\spad{ns}, the number of steps to take.
++
++ \spad{rk4qc(y,n,x1,step,eps,yscal,derivs)} takes a 5-th order
++ Runge-Kutta step with monitoring of local truncation to ensure
++ accuracy and adjust stepsize.
++ The function takes two half steps and one full step and scales
++ the difference in solutions at the final point. If the error is
++ within \spad{eps}, the step is taken and the result is returned.
++ If the error is not within \spad{eps}, the stepsize is decreased
++ and the procedure is tried again until the desired accuracy is
++ reached. Upon input, an trial step size must be given and upon
++ return, an estimate of the next step size to use is returned as
++ well as the step size which produced the desired accuracy.
++ The scaled error is computed as\br
++ \tab{5}\spad{error = MAX(ABS((y2steps(i) - y1step(i))/yscal(i)))}\br
++ and this is compared against \spad{eps}. If this is greater
++ than \spad{eps}, the step size is reduced accordingly to\br
++ \tab{5}\spad{hnew = 0.9 * hdid * (error/eps)**(-1/4)}\br
++ If the error criterion is satisfied, then we check if the

```

```

++ step size was too fine and return a more efficient one. If
++ \spad{error > \spad{eps} * (6.0E-04)} then the next step size should be\br
++ \tab{5}\spad{hnext = 0.9 * hdid * (error/\spad{eps})**(-1/5)}\br
++ Otherwise \spad{hnext = 4.0 * hdid} is returned.
++ A more detailed discussion of this and related topics can be
++ found in the book "Numerical Recipies" by W.Press, B.P. Flannery,
++ S.A. Teukolsky, W.T. Vetterling published by Cambridge University Press.
++
++ Argument \spad{step} is a record of 3 floating point
++ numbers \spad{(try , did , next)},
++ \spad{eps} is the required accuracy,
++ \spad{yscal} is the scaling vector for the difference in solutions.
++ On input, \spad{step.try} should be the guess at a step
++ size to achieve the accuracy.
++ On output, \spad{step.did} contains the step size which achieved the
++ accuracy and \spad{step.next} is the next step size to use.
++
++ \spad{rk4qc(y,n,x1,step,eps,yscal,derivs,t1,t2,t3,t4,t5,t6,t7)} is the
++ same as \spad{rk4qc(y,n,x1,step,eps,yscal,derivs)} except that the user
++ must provide the 7 scratch arrays \spad{t1-t7} of size n.
++
++ \spad{rk4a(y,n,x1,x2,eps,h,ns,derivs)}
++ is a driver program which uses \spad{rk4qc} to integrate n ordinary
++ differential equations starting at x1 to x2, keeping the local
++ truncation error to within \spad{eps} by changing the local step size.
++ The scaling vector is defined as\br
++ \tab{5}\spad{yscal(i) = abs(y(i)) + abs(h*dydx(i)) + tiny}\br
++ where \spad{y(i)} is the solution at location x, \spad{dydx} is the

NumericalQuadrature examples
=====
```

This suite of routines performs numerical quadrature using algorithms derived from the basic trapezoidal rule. Because the error term of this rule contains only even powers of the step size (for open and closed versions), fast convergence can be obtained if the integrand is sufficiently smooth.

Each routine returns a Record of type TrapAns, which contains

|                   |                                          |
|-------------------|------------------------------------------|
| value Float:      | estimate of the integral                 |
| error Float:      | estimate of the error in the computation |
| totalpts Integer: | total number of function evaluations     |

success Boolean: if the integral was computed within the user specified error criterion

To produce this estimate, each routine generates an internal sequence of sub-estimates, denoted by  $S(i)$ , depending on the routine, to which the various convergence criteria are applied. The user must supply a relative accuracy,  $\text{eps}_r$ , and an absolute accuracy,  $\text{eps}_a$ . Convergence is obtained when either

$\text{ABS}(S(i) - S(i-1)) < \text{eps}_r * \text{ABS}(S(i-1))$   
or  
 $\text{ABS}(S(i) - S(i-1)) < \text{eps}_a$   
are true statements.

The routines come in three families and three flavors:

closed: romberg, simpson, trapezoidal  
 open: rombergo, simpsono, trapezoidal0  
 adaptive closed: aromberg, asimpson, atrapezoidal

The  $S(i)$  for the trapezoidal family is the value of the integral using an equally spaced abscissa trapezoidal rule for that level of refinement.

The  $S(i)$  for the simpson family is the value of the integral using an equally spaced abscissa simpson rule for that level of refinement.

The  $S(i)$  for the romberg family is the estimate of the integral using an equally spaced abscissa romberg method. For the  $i$ -th level, this is an appropriate combination of all the previous trapezoidal estimates so that the error term starts with the  $2^{(i+1)}$  power only.

The three families come in a closed version, where the formulas include the endpoints, an open version where the formulas do not include the endpoints and an adaptive version, where the user is required to input the number of subintervals over which the appropriate closed family integrator will apply with the usual convergence parameters for each subinterval. This is useful where a large number of points are needed only in a small fraction of the entire domain.

Each routine takes as arguments:

f integrand  
 a starting point  
 b ending point  
 $\text{eps}_r$  relative error  
 $\text{eps}_a$  absolute error  
 nmin refinement level when to start checking for convergence ( $> 1$ )  
 nmax maximum level of refinement

The adaptive routines take as an additional parameter,  
 nint, the number of independent intervals to apply a closed family integrator of the same name.

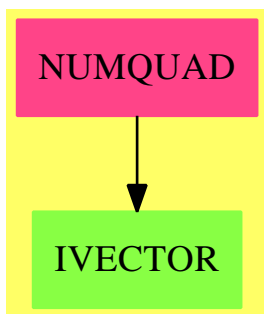

Note that closed family level  $i$  uses  $1 + 2**i$  points.  
 Open family level  $i$  uses  $1 + 3**i$  points.

++ Author: Yuriy A. Baransky
++ Date Created: October 90
++ Date Last Updated: October 90
++ Description:
++ This suite of routines performs numerical quadrature using
++ algorithms derived from the basic trapezoidal rule. Because
++ the error term of this rule contains only even powers of the
++ step size (for open and closed versions), fast convergence
++ can be obtained if the integrand is sufficiently smooth.
++
++ Each routine returns a Record of type TrapAns, which contains
++ value Float: estimate of the integral
++ error Float: estimate of the error in the computation
++ totalpts Integer: total number of function evaluations
++ success Boolean: if the integral was computed within the user
++ specified error criterion
  
```

```

++ To produce this estimate, each routine generates an internal
++ sequence of sub-estimates, denoted by S(i), depending on the
++ routine, to which the various convergence criteria are applied.
++ The user must supply a relative accuracy, \spad{eps_r}, and an absolute
++ accuracy, \spad{eps_a}. Convergence is obtained when either\br
++ \tab{5}\spad{ABS(S(i) - S(i-1)) < eps_r * ABS(S(i-1))}\br
++ \tab{5}or \spad{ABS(S(i) - S(i-1)) < eps_a}
++ are true statements.
++
++ The routines come in three families and three flavors:
++ closed: romberg, simpson, trapezoidal
++ open: rombergo, simpsono, trapezoidal
++ adaptive closed: aromberg, asimpson, atrapezoidal
++
++ The S(i) for the trapezoidal family is the value of the
++ integral using an equally spaced absicca trapezoidal rule for
++ that level of refinement.
++
++ The S(i) for the simpson family is the value of the integral
++ using an equally spaced absicca simpson rule for that level of
++ refinement.
++
++ The S(i) for the romberg family is the estimate of the integral
++ using an equally spaced absicca romberg method. For
++ the i-th level, this is an appropriate combination of all the
++ previous trapezodial estimates so that the error term starts
++ with the 2*(i+1) power only.
++
++ The three families come in a closed version, where the formulas
++ include the endpoints, an open version where the formulas do not
++ include the endpoints and an adaptive version, where the user
++ is required to input the number of subintervals over which the
++ appropriate closed family integrator will apply with the usual
++ convergence parmeters for each subinterval. This is useful
++ where a large number of points are needed only in a small fraction
++ of the entire domain.
++
++ Each routine takes as arguments:\br
++ f integrand\br
++ a starting point\br
++ b ending point\br
++ eps_r relative error\br
++ eps_a absolute error\br
++ nmin refinement level when to start checking for convergence (> 1)\br
++ nmax maximum level of refinement\br
++
++ The adaptive routines take as an additional parameter,
++ nint, the number of independent intervals to apply a closed
++ family integrator of the same name.
++

```

```

++ Notes:\br
++ Closed family level i uses \spad{1 + 2**i} points.\br
++ Open family level i uses \spad{1 + 3**i} points.\br

aromberg : (F -> F,F,F,F,F,I,I,I) -> TrapAns
++ aromberg(fn,a,b,epsrel,epsabs,nmin,nmax,nint)
++ uses the adaptive romberg method to numerically integrate function
++ \spad{fn} over the closed interval from \spad{a} to \spad{b},
++ with relative accuracy \spad{epsrel} and absolute accuracy
++ \spad{epsabs}, with the refinement levels for convergence checking
++ vary from \spad{nmin} to \spad{nmax}, and where \spad{nint}
++ is the number of independent intervals to apply the integrator.
++ The value returned is a record containing the value of the integral,
++ the estimate of the error in the computation, the total number of
++ function evaluations, and either a boolean value which is true if
++ the integral was computed within the user specified error criterion.
++ See \spadtype{NumericalQuadrature} for details.
asimpson : (F -> F,F,F,F,F,I,I,I) -> TrapAns
++ asimpson(fn,a,b,epsrel,epsabs,nmin,nmax,nint) uses the
++ adaptive simpson method to numerically integrate function \spad{fn}
++ over the closed interval from \spad{a} to \spad{b}, with relative
++ accuracy \spad{epsrel} and absolute accuracy \spad{epsabs}, with the
++ refinement levels for convergence checking vary from \spad{nmin}
++ to \spad{nmax}, and where \spad{nint} is the number of independent
++ intervals to apply the integrator. The value returned is a record
++ containing the value of the integral, the estimate of the error in
++ the computation, the total number of function evaluations, and
++ either a boolean value which is true if the integral was computed
++ within the user specified error criterion.
++ See \spadtype{NumericalQuadrature} for details.
atrapezoidal : (F -> F,F,F,F,F,I,I,I) -> TrapAns
++ atrapezoidal(fn,a,b,epsrel,epsabs,nmin,nmax,nint) uses the
++ adaptive trapezoidal method to numerically integrate function
++ \spad{fn} over the closed interval from \spad{a} to \spad{b}, with
++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
++ with the refinement levels for convergence checking vary from
++ \spad{nmin} to \spad{nmax}, and where \spad{nint} is the number
++ of independent intervals to apply the integrator. The value returned

```

```

++ is a record containing the value of the integral, the estimate of
++ the error in the computation, the total number of function
++ evaluations, and either a boolean value which is true if
++ the integral was computed within the user specified error criterion.
++ See \spadtype{NumericalQuadrature} for details.
romberg      : (F -> F,F,F,F,F,I,I) -> TrapAns
++ romberg(fn,a,b,epsrel,epsabs,nmin,nmax) uses the romberg
++ method to numerically integrate function \spadvar{fn} over the closed
++ interval \spad{a} to \spad{b}, with relative accuracy \spad{epsrel}
++ and absolute accuracy \spad{epsabs}, with the refinement levels
++ for convergence checking vary from \spad{nmin} to \spad{nmax}.
++ The value returned is a record containing the value
++ of the integral, the estimate of the error in the computation, the
++ total number of function evaluations, and either a boolean value
++ which is true if the integral was computed within the user specified
++ error criterion. See \spadtype{NumericalQuadrature} for details.
simpson      : (F -> F,F,F,F,F,I,I) -> TrapAns
++ simpson(fn,a,b,epsrel,epsabs,nmin,nmax) uses the simpson
++ method to numerically integrate function \spad{fn} over the closed
++ interval \spad{a} to \spad{b}, with
++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
++ with the refinement levels for convergence checking vary from
++ \spad{nmin} to \spad{nmax}. The value returned
++ is a record containing the value of the integral, the estimate of
++ the error in the computation, the total number of function
++ evaluations, and either a boolean value which is true if
++ the integral was computed within the user specified error criterion.
++ See \spadtype{NumericalQuadrature} for details.
trapezoidal  : (F -> F,F,F,F,F,I,I) -> TrapAns
++ trapezoidal(fn,a,b,epsrel,epsabs,nmin,nmax) uses the
++ trapezoidal method to numerically integrate function \spadvar{fn} over
++ the closed interval \spad{a} to \spad{b}, with relative accuracy
++ \spad{epsrel} and absolute accuracy \spad{epsabs}, with the
++ refinement levels for convergence checking vary
++ from \spad{nmin} to \spad{nmax}. The value
++ returned is a record containing the value of the integral, the
++ estimate of the error in the computation, the total number of
++ function evaluations, and either a boolean value which is true
++ if the integral was computed within the user specified error criterion.
++ See \spadtype{NumericalQuadrature} for details.
rombergo     : (F -> F,F,F,F,F,I,I) -> TrapAns
++ rombergo(fn,a,b,epsrel,epsabs,nmin,nmax) uses the romberg
++ method to numerically integrate function \spad{fn} over
++ the open interval from \spad{a} to \spad{b}, with
++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
++ with the refinement levels for convergence checking vary from
++ \spad{nmin} to \spad{nmax}. The value returned
++ is a record containing the value of the integral, the estimate of
++ the error in the computation, the total number of function
++ evaluations, and either a boolean value which is true if

```

```

++ the integral was computed within the user specified error criterion.
++ See \spadtype{NumericalQuadrature} for details.
simpsono      : (F -> F,F,F,F,F,I,I) -> TrapAns
++ simpsono(fn,a,b,epsrel,epsabs,nmin,nmax) uses the
++ simpson method to numerically integrate function \spad{fn} over
++ the open interval from \spad{a} to \spad{b}, with
++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
++ with the refinement levels for convergence checking vary from
++ \spad{nmin} to \spad{nmax}. The value returned
++ is a record containing the value of the integral, the estimate of
++ the error in the computation, the total number of function
++ evaluations, and either a boolean value which is true if
++ the integral was computed within the user specified error criterion.
++ See \spadtype{NumericalQuadrature} for details.
trapezoidal : (F -> F,F,F,F,F,I,I) -> TrapAns
++ trapezoidal(fn,a,b,epsrel,epsabs,nmin,nmax) uses the
++ trapezoidal method to numerically integrate function \spad{fn}
++ over the open interval from \spad{a} to \spad{b}, with
++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
++ with the refinement levels for convergence checking vary from
++ \spad{nmin} to \spad{nmax}. The value returned
++ is a record containing the value of the integral, the estimate of
++ the error in the computation, the total number of function
++ evaluations, and either a boolean value which is true if
++ the integral was computed within the user specified error criterion.
++ See \spadtype{NumericalQuadrature} for details.

## OneDimensionalArrayFunctions2 (ARRAY12)

### Exports:

map reduce scan

— package ARRAY12 OneDimensionalArrayFunctions2 —

```
)abbrev package ARRAY12 OneDimensionalArrayFunctions2
++ Description:
++ This package provides tools for operating on one-dimensional arrays
++ with unary and binary functions involving different underlying types

OneDimensionalArrayFunctions2(A, B): Exports == Implementation where
  A, B: Type

VA ==> OneDimensionalArray A
VB ==> OneDimensionalArray B
O2 ==> FiniteLinearAggregateFunctions2(A, VA, B, VB)

Exports ==> with
scan    : ((A, B) -> B, VA, B) -> VB
++ scan(f,a,r) successively applies
++ \spad{reduce(f,x,r)} to more and more leading sub-arrays
```

```

++ x of one-dimensional array \spad{a}.
++ More precisely, if \spad{a} is \spad{[a1,a2,...]}, then
++ \spad{scan(f,a,r)} returns
++ \spad{[reduce(f,[a1],r),reduce(f,[a1,a2],r),...]}.
++
++X T1:=OneDimensionalArrayFunctions2(Integer,Integer)
++X adder(a:Integer,b:Integer):Integer == a+b
++X scan(adder,[i for i in 1..10],0)$T1

reduce : ((A, B) -> B, VA, B) -> B
++ reduce(f,a,r) applies function f to each
++ successive element of the
++ one-dimensional array \spad{a} and an accumulant initialized to r.
++ For example, \spad{reduce(_+$Integer,[1,2,3],0)}
++ does \spad{3+(2+(1+0))}. Note that third argument r
++ may be regarded as the identity element for the function f.
++
++X T1:=OneDimensionalArrayFunctions2(Integer,Integer)
++X adder(a:Integer,b:Integer):Integer == a+b
++X reduce(adder,[i for i in 1..10],0)$T1

map : (A -> B, VA) -> VB
++ map(f,a) applies function f to each member of one-dimensional array
++ \spad{a} resulting in a new one-dimensional array over a
++ possibly different underlying domain.
++
++X T1:=OneDimensionalArrayFunctions2(Integer,Integer)
++X map(x+>x+2,[i for i in 1..10])$T1

— package ORTHPOL OrthogonalPolynomialFunctions —

```

)abbrev package ORTHPOL OrthogonalPolynomialFunctions
++ Author: Stephen M. Watt
++ Date Created: 1990
++ Date Last Updated: June 25, 1991
++ Description:
++ This package provides orthogonal polynomials as functions on a ring.

OrthogonalPolynomialFunctions(R: CommutativeRing): Exports == Impl where
  NNI ==> NonNegativeInteger
  RN ==> Fraction Integer

Exports ==> with

chebyshevT: (NNI, R) -> R
++ chebyshevT(n,x) is the n-th Chebyshev polynomial of the first
++ kind, \spad{T[n](x)}. These are defined by
++ \spad{(1-t*x)/(1-2*t*x+t**2) = sum(T[n](x) *t**n, n = 0..)}.

chebyshevU: (NNI, R) -> R
++ chebyshevU(n,x) is the n-th Chebyshev polynomial of the second
++ kind, \spad{U[n](x)}. These are defined by
++ \spad{1/(1-2*t*x+t**2) = sum(T[n](x) *t**n, n = 0..)}.

hermiteH: (NNI, R) -> R
++ hermiteH(n,x) is the n-th Hermite polynomial, \spad{H[n](x)}.
```

```

++ These are defined by
++ \spad{exp(2*t*x-t**2) = sum(H[n](x)*t**n/n!, n = 0..)}.

laguerreL: (NNI, R) -> R
++ laguerreL(n,x) is the n-th Laguerre polynomial, \spad{L[n](x)}.
++ These are defined by
++ \spad{exp(-t*x/(1-t))/(1-t) = sum(L[n](x)*t**n/n!, n = 0..)}.

laguerreL: (NNI, NNI, R) -> R
++ laguerreL(m,n,x) is the associated Laguerre polynomial,
++ \spad{L<m>[n](x)}. This is the m-th derivative of \spad{L[n](x)}.

if R has Algebra RN then
  legendreP: (NNI, R) -> R
    ++ legendreP(n,x) is the n-th Legendre polynomial,
    ++ \spad{P[n](x)}. These are defined by
    ++ \spad{1/sqrt(1-2*x*t+t**2) = sum(P[n](x)*t**n, n = 0..)}.

Exports ==> with
  homogenize: (PolyRing,Integer) -> PolyRing

  interpolateFormsForFact: (DIVISOR,List PolyRing) -> List(PolyRing)

  fullDesTree: () -> Void

  fullInfClsPt: () -> Void

  setCurve: PolyRing -> PolyRing

  projectivePoint: List K -> ProjPt

  pointDominateBy : Plc -> ProjPt
    ++ pointDominateBy(pl) returns the projective point dominated
    ++ by the place pl.

  placesAbove: ProjPt -> List Plc

  setSingularPoints: List ProjPt -> List ProjPt

  goppaCode: (DIVISOR,DIVISOR) -> Matrix K

  goppaCode: (DIVISOR,List(Plc)) -> Matrix K

  rationalPlaces: () -> List Plc
    ++ rationalPlaces returns all the rational places of the
    ++ curve defined by the polynomial given to the package.

  theCurve: () -> PolyRing
    ++ theCurve returns the specified polynomial for the package.

  genus: () -> NNI
    ++ genus returns the genus of the curve defined by the polynomial
    ++ given to the package.

  genusNeg: () -> Integer

```

```

desingTreeWoFullParam : () -> List DesTree
  ++ desingTreeWoFullParam returns the desingularisation trees at all
  ++ singular points of the curve defined by the polynomial given to
  ++ the package. The local parametrizations are not computed.

desingTree: () -> List DesTree
  ++ desingTree returns the desingularisation trees at all singular
  ++ points of the curve defined by the polynomial given to the package.

rationalPoints: () -> List(ProjPt)

singularPoints: () -> List(ProjPt)
  ++ rationalPoints() returns the singular points of the
  ++ curve defined by the polynomial given to the package.
  ++ If the singular points lie in an extension of the specified
  ++ ground field an error message is issued specifying the extension
  ++ degree needed to find all singular points.

parametrize: (PolyRing,Plc) -> PCS
  ++ parametrize(f,pl) returns a local parametrization of f at the place pl.

lBasis: (DIVISOR,NNI) -> List FRACPOLY

lBasis: DIVISOR -> Record(num:List PolyRing, den: PolyRing)
  ++ lBasis computes a basis associated to the specified divisor

findOrderOfDivisor: (DIVISOR,Integer,Integer) -> _
  Record(ord:Integer,num:PolyRing,den:PolyRing,upTo:Integer)

interpolateForms: (DIVISOR,NNI) -> List(PolyRing)
  ++ interpolateForms(d,n) returns a basis of the interpolate forms of
  ++ degree n of the divisor d.

eval: (PolyRing,Plc) -> K
  ++ eval(f,pl) evaluate f at the place pl.

eval: (PolyRing,PolyRing,Plc) -> K
  ++ eval(f,g,pl) evaluate the function f/g at the place pl.

eval: (FRACPOLY,Plc) -> K
  ++ eval(u,pl) evaluate the function u at the place pl.

evalIfCan: (PolyRing,Plc) -> Union(K,"failed")
  ++ evalIfCan(f,pl) evaluate f at the place pl
  ++ (returns "failed" if it is a pole).

evalIfCan: (PolyRing,PolyRing,Plc) -> Union(K,"failed")
  ++ evalIfCan(f,g,pl) evaluate the function f/g at the place pl
  ++ (returns "failed" if it is a pole).

```

```

evalIfCan: (FRACPOLY,Plc) -> Union(K,"failed")
  ++ evalIfCan(u,pl) evaluate the function u at the place pl
  ++ (returns "failed" if it is a pole).

intersectionDivisor: PolyRing -> DIVISOR
  ++ intersectionDivisor(pol) compute the intersection divisor (the
  ++ Cartier divisor) of the form pol with the curve. If some
  ++ intersection points lie in an extension of the ground field,
  ++ an error message is issued specifying the extension degree
  ++ needed to find all the intersection points.
  ++ (If pol is not homogeneous an error message is issued).

adjunctionDivisor: () -> DIVISOR
  ++ adjunctionDivisor computes the adjunction divisor of the plane
  ++ curve given by the polynomial set with the function setCurve.

if K has Finite then --should we say LocallyAlgebraicallyClosedField??

LPolynomial: () -> SparseUnivariatePolynomial Integer
  ++ Returns the L-Polynomial of the curve.

LPolynomial: PI -> SparseUnivariatePolynomial Integer
  ++ LPolynomial(d) returns the L-Polynomial of the curve in
  ++ constant field extension of degree d.

classNumber: () -> Integer
  ++ Returns the class number of the curve.

placesOfDegree: PI -> List Plc
  ++ placesOfDegree(d) returns all places of degree d of the curve.

numberOfPlacesOfDegree: PI -> Integer
  ++ returns the number of places of the given degree

numberRatPlacesExtDeg: PI -> Integer
  ++ numberRatPlacesExtDeg(n) returns the number of rational
  ++ places in the constant field extension of degree n

numberPlacesDegExtDeg: (PI, PI) -> Integer
  ++ numberRatPlacesExtDegExtDeg(d, n) returns the number of
  ++ places of degree d in the constant field extension of degree n

ZetaFunction: () -> UTSZ
  ++ Returns the Zeta function of the curve. Calculated by
  ++ using the L-Polynomial

ZetaFunction: PI -> UTSZ
  ++ Returns the Zeta function of the curve in constant field
  ++ extension. Calculated by using the L-Polynomial

```

```

    translateToOrigin: (PolyRing, ProjPt) -> PolyRing2

    goppaCode: (DIVISOR,DIVISOR) -> Matrix K

    goppaCode: (DIVISOR,List(Plc)) -> Matrix K

    pointDominateBy : Plc -> ProjPt
      ++ pointDominateBy(pl) returns the projective point dominated
      ++ by the place pl.

```

```

placesAbove: ProjPt -> List Plc

projectivePoint: List DK -> ProjPt

setSingularPoints: List ProjPt -> List ProjPt

rationalPlaces: () -> List Plc
  ++ rationalPlaces returns all the rational places of the
  ++ curve defined by the polynomial given to the package.

theCurve: () -> PolyRing
  ++ theCurve returns the specified polynomial for the package.

genus: () -> NNI
  ++ genus returns the genus of the curve defined by the polynomial
  ++ given to the package.

genusNeg: () -> Integer

desingTreeWoFullParam : () -> List DesTree
  ++ desingTreeWoFullParam returns the desingularisation trees at all
  ++ singular points of the curve defined by the polynomial given to
  ++ the package. The local parametrizations are not computed.

desingTree: () -> List DesTree
  ++ desingTree returns the desingularisation trees at all singular points
  ++ of the curve defined by the polynomial given to the package.

rationalPoints: () -> List(ProjPt)

singularPoints: () -> List(ProjPt)
  ++ rationalPoints() returns the singular points of the
  ++ curve defined by the polynomial given to the package.
  ++ If the singular points lie in an extension of the specified
  ++ ground field an error message is issued specifying the extension
  ++ degree needed to find all singular points.

parametrize: (PolyRing,Plc) -> PCS
  ++ parametrize(f,pl) returns a local parametrization of f at the place pl.

lBasis: (DIVISOR,NNI) -> List FracPoly

lBasis: DIVISOR -> Record(num:List PolyRing, den: PolyRing)
  ++ lBasis computes a basis associated to the specified divisor

findOrderOfDivisor: (DIVISOR,Integer,Integer) -> _
  Record(ord:Integer,num:PolyRing,den:PolyRing,upTo:Integer)

interpolateFormsForFact: (DIVISOR,List PolyRing) -> List(PolyRing2)

```

```

interpolateForms: (DIVISOR,NNI) -> List(PolyRing)
  ++ interpolateForms(d,n) returns a basis of the interpolate forms of
  ++ degree n of the divisor d.

eval: (PolyRing,Plc) -> K
  ++ eval(f,pl) evaluate f at the place pl.

eval: (PolyRing,PolyRing,Plc) -> K
  ++ eval(f,g,pl) evaluate the function f/g at the place pl.

eval: (FracPoly,Plc) -> K
  ++ eval(u,pl) evaluate the function u at the place pl.

evalIfCan: (PolyRing,Plc) -> Union(K,"failed")
  ++ evalIfCan(f,pl) evaluate f at the place pl
  ++ (returns "failed" if it is a pole).

evalIfCan: (PolyRing,PolyRing,Plc) -> Union(K,"failed")
  ++ evalIfCan(f,g,pl) evaluate the function f/g at the place pl
  ++ (returns "failed" if it is a pole).

evalIfCan: (FracPoly,Plc) -> Union(K,"failed")
  ++ evalIfCan(u,pl) evaluate the function u at the place pl
  ++ (returns "failed" if it is a pole).

intersectionDivisor: PolyRing -> DIVISOR
  ++ intersectionDivisor(pol) compute the intersection divisor of the
  ++ form pol with the curve.
  ++ (If pol is not homogeneous an error message is issued).

adjunctionDivisor: () -> DIVISOR
  ++ adjunctionDivisor computes the adjunction divisor of the plane
  ++ curve given by the polynomial defined by setCurve.

if DK has Finite then --should we say LocallyAlgebraicallyClosedField??

LPolynomial: () -> SparseUnivariatePolynomial Integer
  ++ Returns the L-Polynomial of the curve.

LPolynomial: PI -> SparseUnivariatePolynomial Integer
  ++ LPolynomial(d) returns the L-Polynomial of the curve in
++ constant field extension of degree d.

classNumber: () -> Integer
  ++ Returns the class number of the curve.

placesOfDegree: PI -> List Plc
  ++ placesOfDegree(d) returns all places of degree d of the
++ curve.

```

```

    numberOfPlacesOfDegree: PI -> Integer
        ++ returns the number of places of the given degree

    numberRatPlacesExtDeg: PI -> Integer
        ++ numberRatPlacesExtDeg(n) returns the number of rational
++ places in the constant field extension of degree n

    numberPlacesDegExtDeg: (PI, PI) -> Integer
        ++ numberRatPlacesExtDegExtDeg(d, n) returns the number of
++ places of degree d in the constant field extension of
++ degree n

    ZetaFunction: () -> UTSZ
        ++ Returns the Zeta function of the curve. Calculated by
++ using the L-Polynomial

    ZetaFunction: PI -> UTSZ
        ++ Returns the Zeta function of the curve in constant field
++ extension. Calculated by using the L-Polynomial

PAdicWildFunctionFieldIntegralBasis examples
=====

```

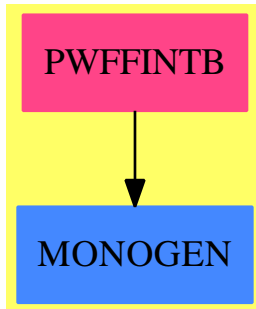

In this package  $K$  is a finite field,  $R$  is a ring of univariate polynomials over  $K$ , and  $F$  is a monogenic algebra over  $R$ .

We require that  $F$  is monogenic, i.e. that  $F = K[x,y]/(f(x,y))$ , because the integral basis algorithm used will factor the polynomial  $f(x,y)$ . The package provides a function to compute the integral closure of  $R$  in the quotient field of  $F$  as well as a function to compute a "local integral basis" at a specific prime.

This package completely solves a parametric linear system of equations by decomposing the set of all parametric values for which the linear system is consistent into a union of quasi-algebraic sets (which need not be irredundant, but most of the time is). Each quasi-algebraic set is described by a list of polynomials that vanish on the set, and a list of polynomials that vanish at no point of the set. For each quasi-algebraic set, the solution of the linear system is given, as a particular solution and a basis of the homogeneous system.

The parametric linear system should be given in matrix form, with a coefficient matrix and a right hand side vector. The entries of the coefficient matrix and right hand side vector should be polynomials in the parametric variables, over a Euclidean domain of characteristic zero.

If the system is homogeneous, the right hand side need not be given. The right hand side can also be replaced by an indeterminate vector, in which case, the conditions required for consistency will also be given.

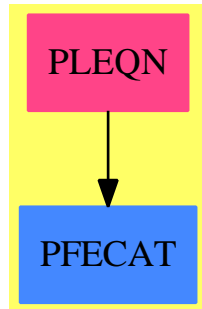

The package has other facilities for saving results to external files, as well as solving the system for a specified minimum rank. Altogether there are 12 mode maps for psolve, as explained below.

-- modified to conform with new runtime system 06/04/90
-- updated with comments for MB, 02/16/94
-- also cleaned up some unnecessary arguments in regime routine
--
-- MB: In order to allow the rhs to be indeterminate, while working
-- mainly with the parametric variables on the lhs (less number of
-- variables), certain conversions of internal representation from
-- GR to Polynomial R and Fraction Polynomial R are done. At the time
-- of implementation, I thought that this may be more efficient. I
-- have not done any comparison since that requires rewriting the
-- package. My own application needs to call this package quite often,
-- and most computations involves only polynomials in the parametric
-- variables.

-- The 12 modes of psolve are probably not all necessary. Again, I
-- was thinking that if there are many regimes and many ranks, then
-- the output is quite big, and it may be nice to be able to save it
-- and read the results in later to continue computing rather than
-- recomputing. Because of the combinatorial nature of the algorithm
-- (computing all subdeterminants!), it does not take a very big matrix
-- to get into many regimes. But I now have second thoughts of this
-- design, since most of the time, the results are just intermediate,
-- passed to be further processed. On the other hand, there is probably
-- no penalty in leaving the options as is.

— package PLEQN ParametricLinearEquations —

```

)abbrev package PLEQN ParametricLinearEquations
++ Author: William Sit, spring 89
++ Description:
++ This package completely solves a parametric linear system of equations
++ by decomposing the set of all parametric values for which the linear
++ system is consistent into a union of quasi-algebraic sets (which need
++ not be irredundant, but most of the time is). Each quasi-algebraic
++ set is described by a list of polynomials that vanish on the set, and
++ a list of polynomials that vanish at no point of the set.
++ For each quasi-algebraic set, the solution of the linear system
++ is given, as a particular solution and a basis of the homogeneous
++ system.
++
++ The parametric linear system should be given in matrix form, with
++ a coefficient matrix and a right hand side vector. The entries
++ of the coefficient matrix and right hand side vector should be
++ polynomials in the parametric variables, over a Euclidean domain
++ of characteristic zero.
++
++ If the system is homogeneous, the right hand side need not be given.
++ The right hand side can also be replaced by an indeterminate vector,
++ in which case, the conditions required for consistency will also be
++ given.
++
++ The package has other facilities for saving results to external
++ files, as well as solving the system for a specified minimum rank.
++ Altogether there are 12 mode maps for psolve, as explained below.

-- MB: The following macros are data structures to store mostly
-- intermediate results
-- Rec stores a subdeterminant with corresponding row and column indices
-- Fgb is a Groebner basis for the ideal generated by the subdeterminants
--   of a given rank.
-- Linsys specifies a linearly independent system of a given system
--   assuming a given rank, using given row and column indices
-- Linsoln stores the solution to the parametric linear system as a basis
--   and a particular solution (for a given regime)
-- Rec2 stores the rank, and a list of subdeterminants of that rank,
--   and a Groebner basis for the ideal they generate.
-- Rec3 stores a regime and the corresponding solution; the regime is
--   given by a list of equations (eqzro) and one inequation (neqzro)
--   describing the quasi-algebraic set which is the regime; the
--   additional consistency conditions due to the rhs is given by wcond.
-- Ranksolns stores a list of regimes and their solutions, and the number
--   of regimes all together.
-- Rec8 (temporary) stores a quasi-algebraic set with an indication
-- whether it is empty (sysok = false) or not (sysok = true).

-- I think psolve should be renamed parametricSolve, or even
-- parametricLinearSolve. On the other hand, may be just solve will do.
-- Please feel free to change it to conform with system conventions.
-- Most psolve routines return a list of regimes and solutions,
-- except those that output to file when the number of regimes is
-- returned instead.
-- This version has been tested on the pc version 1.608 March 13, 1992

-- for internal use only --
-- these are exported so my other packages can use them

bsolve: (M GR, L GF, NNI, S, Inputmode) -> Ranksolns
++ bsolve(c, w, r, s, m) returns a list of regimes and
++ solutions of the system  $c z = w$  for ranks at least  $r$ ;
++ depending on the mode  $m$  chosen, it writes the output to
++ a file given by the string  $s$ .
dmp2rfi: GR -> GF
++ dmp2rfi(p) converts  $p$  to target domain
dmp2rfi: M GR -> M GF
++ dmp2rfi(m) converts  $m$  to target domain
dmp2rfi: L GR -> L GF
++ dmp2rfi(l) converts  $l$  to target domain
se2rfi: L Symbol -> L GF
++ se2rfi(l) converts  $l$  to target domain
pr2dmp: PR -> GR
++ pr2dmp(p) converts  $p$  to target domain
hasoln: (Fgb, L GR) -> Rec8
++ hasoln(g, l) tests whether the quasi-algebraic set
++ defined by  $p = 0$  for  $p$  in  $g$  and  $q \neq 0$  for  $q$  in  $l$ 
++ is empty or not and returns a simplified definition
++ of the quasi-algebraic set
-- this is now done in QALGSET package
ParCondList: (M GR,NNI) -> RankConds
++ ParCondList(c,r) computes a list of subdeterminants of each
++ rank  $\geq r$  of the matrix  $c$  and returns
++ a groebner basis for the
++ ideal they generate
redpps: (Linsoln, Fgb) -> Linsoln

```

```

++ redpps(s,g) returns the simplified form of s after reducing
++ modulo a groebner basis g

```

-- LOCAL FUNCTIONS

```

Bisolve: Linsys -> Linsoln
++ Bisolve(s) solves the system (s.mat) z = s.vec
++ for the variables given by the column indices of s.cols
++ in terms of the other variables and the right hand side s.vec
++ by assuming that the rank is s.rank,
++ that the system is consistent, with the linearly
++ independent equations indexed by the given row indices s.rows;
++ the coefficients in s.mat involving parameters are treated as
++ polynomials. Bisolve(s) returns a particular solution to the
++ system and a basis of the homogeneous system (s.mat) z = 0.
factorset: GR -> L GR
++ factorset(p) returns the set of irreducible factors of p.
maxrank: RankConds -> NNI
++ maxrank(r) returns the maximum rank in the list r of regimes
minrank: RankConds -> NNI
++ minrank(r) returns the minimum rank in the list r of regimes
minset: L L GR -> L L GR
++ minset(sl) returns the sublist of sl consisting of the minimal
++ lists (with respect to inclusion) in the list sl of lists
nextSublist: (I, I) -> L L I
++ nextSublist(n,k) returns a list of k-subsets of {1, ..., n}.
overset?: (L GR, L L GR) -> Boolean
++ overset?(s,sl) returns true if s properly a sublist of a member
++ of sl; otherwise it returns false
ParCond : (M GR,NNI) -> Eqns
++ ParCond(m,k) returns the list of all k by k subdeterminants in
++ the matrix m
redmat: (M GR, Fgb) -> M GR
++ redmat(m,g) returns a matrix whose entries are those of m
++ modulo the ideal generated by the groebner basis g
regime: (Rec,M GR,L GF,L L GR,NNI,NNI,Inputmode) -> Rec3
++ regime(y,c, w, p, r, rm, m) returns a regime,
++ a list of polynomials specifying the consistency conditions,
++ a particular solution and basis representing the general
++ solution of the parametric linear system c z = w
++ on that regime. The regime returned depends on
++ the subdeterminant y.det and the row and column indices.
++ The solutions are simplified using the assumption that
++ the system has rank r and maximum rank rm. The list p
++ represents a list of list of factors of polynomials in
++ a groebner basis of the ideal generated by higher order
++ subdeterminants, and ius used for the simplification.
++ The mode m

```

```

    ++ distinguishes the cases when the system is homogeneous,
    ++ or the right hand side is arbitrary, or when there is no
    ++ new right hand side variables.
sqfree: GR -> GR
    ++ sqfree(p) returns the product of square free factors of p
inconsistent?: L GR -> Boolean
    ++ inconsistent?(pl) returns true if the system of equations
    ++ p = 0 for p in pl is inconsistent. It is assumed
    ++ that pl is a groebner basis.
    -- this is needed because of change to
    -- EuclideanGroebnerBasisPackage
inconsistent?: L PR -> Boolean
    ++ inconsistent?(pl) returns true if the system of equations
    ++ p = 0 for p in pl is inconsistent. It is assumed
    ++ that pl is a groebner basis.
    -- this is needed because of change to
    -- EuclideanGroebnerBasisPackage

```

=====
PartialFractionPackage examples
=====

```

The package PartialFractionPackage gives an easier to use interface to the domain PartialFraction. The user gives a fraction of polynomials, and a variable and the package converts it to the proper datatype for the PartialFraction domain.

When Axiom is given an expression such as:

```
a:=x+1/(y+1)
```

it will end up with the result in Fraction Polynomial Integer.

$$\frac{xy + x + 1}{y + 1}$$

We might want it in a partial fraction form. This can be done with:

```
partialFraction(a,y)$PFRPAC(INT)
```

$$x + \frac{1}{y + 1}$$

We can do the same thing with a different variable:

```
b:=y+1/(x+1)
```

$$\frac{(x + 1)y + 1}{x + 1}$$

```
partialFraction(b,x)$PFRPAC(INT)
```

$$y + \frac{1}{x + 1}$$

conjugates: ST L I -> ST L I
++\spad{conjugates(lp)} is the stream of conjugates of a stream
++ of partitions lp.
shuffle: (L I,L I) -> ST L I
++\spad{shuffle(l1,l2)} forms the stream of all shuffles of l1
++ and l2, i.e. all sequences that can be formed from
++ merging l1 and l2.
shufflein: (L I,ST L I) -> ST L I
++\spad{shufflein(l,st)} maps shuffle(l,u) on to all
++ members u of st, concatenating the results.
sequences: (L I,L I) -> ST L I
++\spad{sequences(l1,l2)} is the stream of all sequences that
++ can be composed from the multiset defined from
++ two lists of integers l1 and l2.
++ For example, the pair \spad{([1,2,4],[2,3,5])} represents
++ multi-set with 1 \spad{2}, 2 \spad{3}'s, and 4 \spad{5}'s.
sequences: L I -> ST L I
++ \spad{sequences([l0,l1,l2,...,ln])} is the set of
++ all sequences formed from
++ \spad{l0} 0's, \spad{l1} 1's, \spad{l2} 2's, ..., \spad{ln} n's.
permutations: I -> ST L I
++\spad{permutations(n)} is the stream of permutations
++ formed from \spad{1,2,3,...,n}.

```

### PatternMatchIntegration (INTPM)

#### Exports:

pmComplexintegrate pmintegrate pmintegrate splitConstant

— package INTPM PatternMatchIntegration —

```

)abbrev package INTPM PatternMatchIntegration
++ Author: Manuel Bronstein
++ Date Created: 5 May 1992
++ Date Last Updated: 27 September 1995
++ Description:
++ \spadtype{PatternMatchIntegration} provides functions that use
++ the pattern matcher to find some indefinite and definite integrals
++ involving special functions and found in the literature.
  
```

```

PatternMatchIntegration(R, F): Exports == Implementation where
  R : Join(OrderedSet, RetractableTo Integer, GcdDomain,
    LinearlyExplicitRingOver Integer)
  F : Join(AlgebraicallyClosedField, TranscendentalFunctionCategory,
    FunctionSpace R)
  
```

```

N ==> NonNegativeInteger
Z ==> Integer
SY ==> Symbol
K ==> Kernel F
P ==> SparseMultivariatePolynomial(R, K)
SUP ==> SparseUnivariatePolynomial F
PAT ==> Pattern Z
RES ==> PatternMatchResult(Z, F)
OFE ==> OrderedCompletion F
REC ==> Record(which: Z, exponent: F, coeff: F)
ANS ==> Record(special:F, integrand:F)
NONE ==> 0
EI ==> 1
ERF ==> 2
SI ==> 3
CI ==> 4
GAM2 ==> 5
CIO ==> 6

Exports ==> with
  splitConstant: (F, SY) -> Record(const:F, nconst:F)
  ++ splitConstant(f, x) returns \spad{[c, g]} such that
  ++ \spad{f = c * g} and \spad{c} does not involve \spad{t}.
  if R has ConvertibleTo Pattern Integer and
  R has PatternMatchable Integer then
    if F has LiouvillianFunctionCategory then
      pmComplexintegrate: (F, SY) -> Union(ANS, "failed")
      ++ pmComplexintegrate(f, x) returns either "failed" or
      ++ \spad{[g,h]} such that
      ++ \spad{integrate(f,x) = g + integrate(h,x)}.
      ++ It only looks for special complex integrals that pminegrate
      ++ does not return.
      pmintegrate: (F, SY) -> Union(ANS, "failed")
      ++ pmintegrate(f, x) returns either "failed" or \spad{[g,h]} such
      ++ that \spad{integrate(f,x) = g + integrate(h,x)}.
    if F has SpecialFunctionCategory then
      pmintegrate: (F, SY, OFE, OFE) -> Union(F, "failed")
      ++ pmintegrate(f, x = a..b) returns the integral of
      ++ \spad{f(x)dx} from a to b
      ++ if it can be found by the built-in pattern matching rules.

Implementation ==> add

## PatternMatchPolynomialCategory (PMPLCAT)

### Exports:

patternMatch

— package PMPLCAT PatternMatchPolynomialCategory —

```

)abbrev package PMPLCAT PatternMatchPolynomialCategory
++ Author: Manuel Bronstein
++ Date Created: 9 Jan 1990
++ Date Last Updated: 20 June 1991
++ Description:
++ This package provides pattern matching functions on polynomials.

PatternMatchPolynomialCategory(S,E,V,R,P):Exports== Implementation where
  S: SetCategory
  E: OrderedAbelianMonoidSup
  V: OrderedSet
  R: Join(Ring, OrderedSet, PatternMatchable S)
  P: Join(PolynomialCategory(R, E, V), ConvertibleTo Pattern S)

N ==> NonNegativeInteger
PAT ==> Pattern S
PRS ==> PatternMatchResult(S, P)
RCP ==> Record(val:PAT, exponent:N)
RCX ==> Record(var:V, exponent:N)

Exports ==> with
  patternMatch: (P, PAT, PRS, (V, PAT, PRS) -> PRS) -> PRS
    ++ patternMatch(p, pat, res, vmatch) matches the pattern pat to
    ++ the polynomial p. res contains the variables of pat which
    ++ are already matched and their matches; vmatch is the matching
    ++ function to use on the variables.
    -- This can be more efficient than pushing down when the variables
    -- are recursive over P (e.g. kernels)
  if V has PatternMatchable S then
    patternMatch: (P, PAT, PRS) -> PRS
  
```

```

++ patternMatch(p, pat, res) matches the pattern pat to
++ the polynomial p; res contains the variables of pat which
++ are already matched and their matches.

```

```

Implementation ==> add
import PatternMatchTools(S, R, P)
import PatternMatchPushDown(S, R, P)

if V has PatternMatchable S then
  patternMatch(x, p, l) ==
    patternMatch(x, p, l, patternMatch$PatternMatchPushDown(S,V,P))

=====

Permanent examples

=====

The package Permanent provides the function permanent for square matrices. The permanent of a square matrix can be computed in the same way as the determinant by expansion of minors except that for the permanent the sign for each element is 1, rather than being 1 if the row plus column indices is positive and -1 otherwise. This function is much more difficult to compute efficiently than the determinant. An example of the use of permanent is the calculation of the n-th derangement number, defined to be the number of different possibilities for n couples to dance but never with their own spouse.

Consider an n by n matrix with entries 0 on the diagonal and 1 elsewhere. Think of the rows as one-half of each couple (for example, the males) and the columns the other half. The permanent of such a matrix gives the desired derangement number.

```

kn n ==
  r : MATRIX INT := new(n,n,1)
  for i in 1..n repeat
    r.i.i := 0
  r

```

Here are some derangement numbers, which you see grow quite fast.

```

permanent(kn(5) :: SQMATRIX(5,INT))

```

```

[permanent(kn(n) :: SQMATRIX(n,INT)) for n in 1..13]

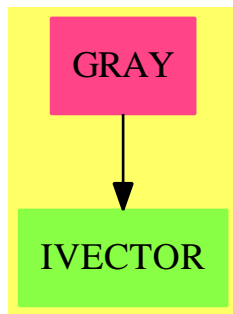

```

++   S.G.Williamson, Combinatorics for Computer Science,
++   Computer Science Press, 1985.
++ Description:
++ Permanent implements the functions permanent, the
++ permanent for square matrices.

Permanent(n : PositiveInteger, R : Ring with commutative("*")):
  public == private where
    I ==> Integer
    L ==> List
    V ==> Vector
    SM ==> SquareMatrix(n,R)
  
```

```

VECTPKG1 ==> VectorPackage1(I)
NNI ==> NonNegativeInteger
PI ==> PositiveInteger
GRAY ==> GrayCode

public ==> with

permanent: SM -> R
  ++ permanent(x) computes the permanent of a square matrix x.
  ++ The permanent is equivalent to
  ++ the \spadfun{determinant} except that coefficients have
  ++ no change of sign. This function
  ++ is much more difficult to compute than the
  ++ determinant. The formula used is by H.J. Ryser,
  ++ improved by [Nijenhuis and Wilf, Ch. 19].
  ++ Note that permanent(x) choose one of three algorithms, depending
  ++ on the underlying ring R and on n, the number of rows (and
  ++ columns) of x:\br
  ++ if 2 has an inverse in R we can use the algorithm of
  ++ [Nijenhuis and Wilf, ch.19,p.158]; if 2 has no inverse,
  ++ some modifications are necessary:\br
  ++ if n > 6 and R is an integral domain with characteristic
  ++ different from 2 (the algorithm works if and only 2 is not a
  ++ zero-divisor of R and characteristic()$R ^= 2,
  ++ but how to check that for any given R ?),
  ++ the local function permanent2 is called;\br
  ++ else, the local function permanent3 is called
  ++ (works for all commutative rings R).

rubiksGroup:     ()          -> PERMGRP I
++ rubiksGroup constructs the permutation group representing
++ Rubik's Cube acting on integers 10*i+j for
++ 1 <= i <= 6, 1 <= j <= 8.
++ The faces of Rubik's Cube are labelled in the obvious way
++ Front, Right, Up, Down, Left, Back and numbered from 1 to 6
++ in this given ordering, the pieces on each face
++ (except the unmoveable center piece) are clockwise numbered
++ from 1 to 8 starting with the piece in the upper left
++ corner. The moves of the cube are represented as permutations
++ on these pieces, represented as a two digit
++ integer ij where i is the number of the face (1 to 6)
++ and j is the number of the piece on this face.
++ The remaining ambiguities are resolved by looking
++ at the 6 generators, which represent a 90 degree turns of the
++ faces, or from the following pictorial description.
++ Permutation group representing Rubik's Cube acting on integers
++ 10*i+j for 1 <= i <= 6, 1 <= j <= 8.
++
++ \begin{verbatim}
++ Rubik's Cube:  +-----+ +--- B   where: marks Side # :
++                / U   //
++                /   / |           F(ront)    <->    1
++      L --> +-----+ R|           R(ight)    <->    2
++                |   | +           U(p)       <->    3
++                | F | /           D(own)     <->    4
++                |   | /           L(eft)     <->    5
++                +-----+         B(ack)     <->    6
++                ^
++                |
++                D
++
++ The Cube's surface:
++
++                +----+
++                |567|
++                |408|
++                |321|
++      +-----+-----+
++      |781|123|345|
++      |6L2|8F4|2R6|
++      |543|765|187|
++      +-----+-----+
++      |123|
++      |8D4|

```

The pieces on each side  
(except the unmoveable center  
piece) are clockwise numbered  
from 1 to 8 starting with the  
piece in the upper left  
corner (see figure on the  
left). The moves of the cube  
are represented as  
permutations on these pieces.  
Each of the pieces is  
represented as a two digit  
integer ij where i is the

```

++          |765|          # of the side ( 1 to 6 for
++          +---+          F to B (see table above ))
++          |567|          and j is the # of the piece.
++          |4B8|
++          |321|
++          +---+
++ \end{verbatim}
youngGroup:      L I      -> PERMGRP I
++ youngGroup([n1,...,nk]) constructs the direct product of the
++ symmetric groups Sn1,...,Snk.
youngGroup:      Partition      -> PERMGRP I
++ youngGroup(lambda) constructs the direct product of the symmetric
++ groups given by the parts of the partition lambda.

```

This package is an interface package to the groebner basis package which allows you to compute groebner bases for polynomials in either lexicographic ordering or total degree ordering refined by reverse lex. The input is the ordinary polynomial type which is internally converted to a type with the required ordering. The resulting grobner basis is converted back to ordinary polynomials. The ordering among the variables is controlled by an explicit list of variables which is passed as a second argument. The coefficient domain is allowed to be any gcd domain, but the groebner basis is computed as if the polynomials were over a field.

gcd gcdPrimitive

The simple Euclidean division algorithm,

**given**  $a \neq 0$ ,  $b \neq 0$  where  $a$  and  $b$  are two polynomials in the variable  $x$ , then

**output**  $q$ , the quotient and  $r$ , the remainder

**begin**

**Let**

$q = 0$

$r = a$

$d = \text{degree}(b)$

$c = \text{leadingCoefficient}(b)$

**while**  $\text{degree}(r) \geq d$  **do**

$e = \text{degree}(r) - d$

$s = \frac{\text{leadingCoefficient}(r)}{c} x^e$

$q = q + s$

$r = r - sb$

**endwhile**

**return**( $q, r$ )

**end**

For example, given

$p1 := (x+1) * (x+6)$

$p2 := (x+1) * (x-6)$

$\text{gcd}(p1, p2) \rightarrow x+1$

---

In Gathen [?] we find a discussion of applying the Euclidean algorithm to elements of a field. In a field every nonzero rational number is a unit. If we want to define a single element such that

$$\gcd(f, g) \in \mathbb{Q}[x]$$

we choose a monic polynomial, that is, the element with a leading coefficient of 1. So

$$\text{abs}(a / \text{leadingCoefficient}(a))$$

defines a normal form of  $a$ .

Gathen also notes that for polynomials we should modify the Euclidean algorithm so *all* remainders are normalized. Without this constraint the remainders will have huge numerators

and denominators.

```

---

Hensel's lifting lemma states that if a polynomial equation has a simple root modulo a prime number  $p$ , then this root corresponds to a unique root of the same equation modulo any higher power of  $p$ , which can be found by iteratively "lifting" the solution modulo successive powers of  $p$ .

See Volume 10.1 for more details.

```

```

Exports ==> with
bernoulli : I -> SUP RN
  ++ bernoulli(n) returns the nth Bernoulli polynomial \spad{B[n](x)}.
  ++ Bernoulli polynomials denoted \spad{B(n,x)} computed by solving the
  ++ differential equation \spad{differentiate(B(n,x),x) = n B(n-1,x)} where
  ++ \spad{B(0,x) = 1} and initial condition comes from \spad{B(n) = B(n,0)}.
chebyshevT: I -> SUP I
  ++ chebyshevT(n) returns the nth Chebyshev polynomial \spad{T[n](x)}.
  ++ Note that Chebyshev polynomials of the first kind,
  ++ denoted \spad{T[n](x)},
  ++ computed from the two term recurrence. The generating function
  ++ \spad{(1-t*x)/(1-2*t*x+t**2) = sum(T[n](x)*t**n, n=0..infinity)}.
chebyshevU: I -> SUP I
  ++ chebyshevU(n) returns the nth Chebyshev polynomial \spad{U[n](x)}.

```

```

++ Note that Chebyshev polynomials of the second kind,
++ denoted \spad{U[n](x)},
++ computed from the two term recurrence. The generating function
++ \spad{1/(1-2*t*x+t**2) = sum(T[n](x)*t**n, n=0..infinity)}.
cyclotomic: I -> SUP I
++ cyclotomic(n) returns the nth cyclotomic polynomial \spad{phi[n](x)}.
++ Note that \spad{phi[n](x)} is the factor of \spad{x**n - 1} whose roots
++ are the primitive nth roots of unity.
euler      : I -> SUP RN
++ euler(n) returns the nth Euler polynomial \spad{E[n](x)}.
++ Note that Euler polynomials denoted \spad{E(n,x)} computed by solving
++ the differential equation
++ \spad{differentiate(E(n,x),x) = n E(n-1,x)} where
++ \spad{E(0,x) = 1} and initial condition comes
++ from \spad{E(n) = 2**n E(n,1/2)}.
fixedDivisor: SUP I -> I
++ fixedDivisor(a) for \spad{a(x)} in \spad{Z[x]} is the largest integer
++ f such that f divides \spad{a(x=k)} for all integers k.
++ Note that fixed divisor of \spad{a} is
++ \spad{reduce(gcd,[a(x=k) for k in 0..degree(a)])}.
hermite    : I -> SUP I
++ hermite(n) returns the nth Hermite polynomial \spad{H[n](x)}.
++ Note that Hermite polynomials, denoted \spad{H[n](x)}, are computed from
++ the two term recurrence. The generating function is:
++ \spad{exp(2*t*x-t**2) = sum(H[n](x)*t**n/n!, n=0..infinity)}.
laguerre   : I -> SUP I
++ laguerre(n) returns the nth Laguerre polynomial \spad{L[n](x)}.
++ Note that Laguerre polynomials, denoted \spad{L[n](x)}, are computed
++ from the two term recurrence. The generating function is:
++ \spad{exp(x*t/(t-1))/(1-t) = sum(L[n](x)*t**n/n!, n=0..infinity)}.
legendre   : I -> SUP RN
++ legendre(n) returns the nth Legendre polynomial \spad{P[n](x)}.
++ Note that Legendre polynomials, denoted \spad{P[n](x)}, are computed
++ from the two term recurrence. The generating function is:
++ \spad{1/sqrt(1-2*t*x+t**2) = sum(P[n](x)*t**n, n=0..infinity)}.

removeRedundantFactors: LP -> LP
++ \axiom{removeRedundantFactors(lp)} returns \axiom{lq} such that if
++ \axiom{lp = [p1,...,pn]} and \axiom{lq = [q1,...,qm]}
++ then the product \axiom{p1*p2*...*pn} vanishes iff the product \axiom{q1*q2*...*qm} v
++ and the product of degrees of the \axiom{qi} is not greater than
++ the one of the \axiom{pj}, and no polynomial in \axiom{lq}
++ divides another polynomial in \axiom{lq}. In particular,
++ polynomials lying in the base ring \axiom{R} are removed.
++ Moreover, \axiom{lq} is sorted w.r.t \axiom{infRittWu?}.
++ Furthermore, if R is gcd-domain, the polynomials in \axiom{lq} are
++ pairwise without common non trivial factor.
removeRedundantFactors: (P,P) -> LP
++ \axiom{removeRedundantFactors(p,q)} returns the same as
++ \axiom{removeRedundantFactors([p,q])}
removeSquaresIfCan : LP -> LP
++ \axiom{removeSquaresIfCan(lp)} returns
++ \axiom{removeDuplicates [squareFreePart(p)$P for p in lp]}
++ if \axiom{R} is gcd-domain else returns \axiom{lp}.
unprotectedRemoveRedundantFactors: (P,P) -> LP
++ \axiom{unprotectedRemoveRedundantFactors(p,q)} returns the same as
++ \axiom{removeRedundantFactors(p,q)} but does assume that neither
++ \axiom{p} nor \axiom{q} lie in the base ring \axiom{R} and assumes that
++ \axiom{infRittWu?(p,q)} holds. Moreover, if \axiom{R} is gcd-domain,
++ then \axiom{p} and \axiom{q} are assumed to be square free.
removeRedundantFactors: (LP,P) -> LP
++ \axiom{removeRedundantFactors(lp,q)} returns the same as
++ \axiom{removeRedundantFactors(cons(q,lp))} assuming
++ that \axiom{removeRedundantFactors(lp)} returns \axiom{lp}
++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
++ by some some polynomial \axiom{qj} associated to \axiom{pj}.
removeRedundantFactors : (LP,LP) -> LP
++ \axiom{removeRedundantFactors(lp,lq)} returns the same as
++ \axiom{removeRedundantFactors(concat(lp,lq))} assuming
++ that \axiom{removeRedundantFactors(lp)} returns \axiom{lp}
++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
++ by some polynomial \axiom{qj} associated to \axiom{pj}.
removeRedundantFactors : (LP,LP,(LP -> LP)) -> LP
++ \axiom{removeRedundantFactors(lp,lq,remOp)} returns the same as
++ \axiom{concat(remOp(removeRoughlyRedundantFactorsInPolys(lp,lq)),lq)}
++ assuming that \axiom{remOp(lq)} returns \axiom{lq} up to similarity.
certainlySubVariety? : (LP,LP) -> B
++ \axiom{certainlySubVariety?(newlp,lp)} returns true iff for every \axiom{p}
++ in \axiom{lp} the remainder of \axiom{p} by \axiom{newlp} using the division algorithm
++ of Groebner techniques is zero.
possiblyNewVariety? : (LP, List LP) -> B
++ \axiom{possiblyNewVariety?(newlp,llp)} returns true iff for every \axiom{lp}
++ in \axiom{llp} certainlySubVariety?(newlp,lp) does not hold.
probablyZeroDim?: LP -> B
++ \axiom{probablyZeroDim?(lp)} returns true iff the number of polynomials
++ in \axiom{lp} is not smaller than the number of variables occurring

```

```

++ in these polynomials.
selectPolynomials : ((P -> B),LP) -> Record(goodPols:LP,badPols:LP)
++ \axiom{selectPolynomials(pred?,ps)} returns \axiom{gps,bps} where
++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
++ such that \axiom{pred?(p)} holds and \axiom{bps} are the other ones.
selectOrPolynomials : (List (P -> B),LP) -> Record(goodPols:LP,badPols:LP)
++ \axiom{selectOrPolynomials(lpred?,ps)} returns \axiom{gps,bps} where
++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
++ such that \axiom{pred?(p)} holds for some \axiom{pred?} in \axiom{lpred?}
++ and \axiom{bps} are the other ones.
selectAndPolynomials : (List (P -> B),LP) -> Record(goodPols:LP,badPols:LP)
++ \axiom{selectAndPolynomials(lpred?,ps)} returns \axiom{gps,bps} where
++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
++ such that \axiom{pred?(p)} holds for every \axiom{pred?} in \axiom{lpred?}
++ and \axiom{bps} are the other ones.
quasiMonicPolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \axiom{quasiMonicPolynomials(lp)} returns \axiom{qmps,nqmps} where
++ \axiom{qmps} is a list of the quasi-monic polynomials in \axiom{lp}
++ and \axiom{nqmps} are the other ones.
univariate? : P -> B
++ \axiom{univariate?(p)} returns true iff \axiom{p} involves one and
++ only one variable.
univariatePolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \axiom{univariatePolynomials(lp)} returns \axiom{ups,nups} where
++ \axiom{ups} is a list of the univariate polynomials,
++ and \axiom{nups} are the other ones.
linear? : P -> B
++ \axiom{linear?(p)} returns true iff \axiom{p} does not lie
++ in the base ring \axiom{R} and has main degree \axiom{1}.
linearPolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \axiom{linearPolynomials(lp)} returns \axiom{lps,nlps} where
++ \axiom{lps} is a list of the linear polynomials in lp,
++ and \axiom{nlps} are the other ones.
bivariate? : P -> B
++ \axiom{bivariate?(p)} returns true iff \axiom{p} involves two and
++ only two variables.
bivariatePolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \axiom{bivariatePolynomials(lp)} returns \axiom{bps,nbps} where
++ \axiom{bps} is a list of the bivariate polynomials,
++ and \axiom{nbps} are the other ones.
removeRoughlyRedundantFactorsInPols : (LP, LP) -> LP
++ \axiom{removeRoughlyRedundantFactorsInPols(lp,lf)} returns
++ \axiom{newlp} where \axiom{newlp} is obtained from \axiom{lp}
++ by removing in every polynomial \axiom{p} of \axiom{lp}
++ any occurrence of a polynomial \axiom{f} in \axiom{lf}.
++ This may involve a lot of exact-quotients computations.
removeRoughlyRedundantFactorsInPols : (LP, LP,B) -> LP
++ \axiom{removeRoughlyRedundantFactorsInPols(lp,lf,opt)} returns
++ the same as \axiom{removeRoughlyRedundantFactorsInPols(lp,lf)}
++ if \axiom{opt} is \axiom{false} and if the previous operation

```

```

    ++ does not return any non null and constant polynomial,
    ++ else return \axiom{[1]}.
removeRoughlyRedundantFactorsInPol : (P,LP) -> P
    ++ \axiom{removeRoughlyRedundantFactorsInPol(p,lf)} returns the same as
    ++ removeRoughlyRedundantFactorsInPols([p],lf,true)
interReduce: LP -> LP
    ++ \axiom{interReduce(lp)} returns \axiom{lp} such that \axiom{lp}
    ++ and \axiom{lp} generate the same ideal and no polynomial
    ++ in \axiom{lp} is reducible by the others in the sense
    ++ of Groebner bases. Since no assumptions are required
    ++ the result may depend on the ordering the reductions are
    ++ performed.
roughBasicSet: LP -> Union(Record(bas:T,top:LP),"failed")
    ++ \axiom{roughBasicSet(lp)} returns the smallest (with Ritt-Wu
    ++ ordering) triangular set contained in \axiom{lp}.
crushedSet: LP -> LP
    ++ \axiom{crushedSet(lp)} returns \axiom{lp} such that \axiom{lp} and
    ++ and \axiom{lp} generate the same ideal and no rough basic
    ++ sets reduce (in the sense of Groebner bases) the other
    ++ polynomials in \axiom{lp}.
rewriteSetByReducingWithParticularGenerators : (LP,(P->B),((P,P)->B),((P,P)->P)) -> LP
    ++ \axiom{rewriteSetByReducingWithParticularGenerators(lp,pred?,redOp?,redOp)}
    ++ returns \axiom{lp} where \axiom{lp} is computed by the following
    ++ algorithm. Chose a basic set w.r.t. the reduction-test \axiom{redOp?}
    ++ among the polynomials satisfying property \axiom{pred?},
    ++ if it is empty then leave, else reduce the other polynomials by
    ++ this basic set w.r.t. the reduction-operation \axiom{redOp}.
    ++ Repeat while another basic set with smaller rank can be computed.
    ++ See code. If \axiom{pred?} is \axiom{quasiMonic?} the ideal is unchanged.
rewriteIdealWithQuasiMonicGenerators : (LP,((P,P)->B),((P,P)->P)) -> LP
    ++ \axiom{rewriteIdealWithQuasiMonicGenerators(lp,redOp?,redOp)} returns
    ++ \axiom{lp} where \axiom{lp} and \axiom{lp} generate
    ++ the same ideal in \axiom{R-1 P} and \axiom{lp}
    ++ has rank not higher than the one of \axiom{lp}.
    ++ Moreover, \axiom{lp} is computed by reducing \axiom{lp}
    ++ w.r.t. some basic set of the ideal generated by
    ++ the quasi-monic polynomials in \axiom{lp}.
if R has GcdDomain
then
    squareFreeFactors : P -> LP
        ++ \axiom{squareFreeFactors(p)} returns the square-free factors of \axiom{p}
        ++ over \axiom{R}
    univariatePolynomialsGcds : LP -> LP
        ++ \axiom{univariatePolynomialsGcds(lp)} returns \axiom{lg} where
        ++ \axiom{lg} is a list of the gcds of every pair in \axiom{lp}
        ++ of univariate polynomials in the same main variable.
    univariatePolynomialsGcds : (LP,B) -> LP
        ++ \axiom{univariatePolynomialsGcds(lp,opt)} returns the same as
        ++ \axiom{univariatePolynomialsGcds(lp)} if \axiom{opt} is
        ++ \axiom{false} and if the previous operation does not return

```

```

    ++ any non null and constant polynomial, else return \axiom{[1]}.
removeRoughlyRedundantFactorsInContents : (LP, LP) -> LP
    ++ \axiom{removeRoughlyRedundantFactorsInContents(lp,lf)} returns
    ++ \axiom{newlp} where \axiom{newlp} is obtained from \axiom{lp}
    ++ by removing in the content of every polynomial of \axiom{lp}
    ++ any occurrence of a polynomial \axiom{f} in \axiom{lf}. Moreover,
    ++ squares over \axiom{R} are first removed in the content
    ++ of every polynomial of \axiom{lp}.
removeRedundantFactorsInContents : (LP, LP) -> LP
    ++ \axiom{removeRedundantFactorsInContents(lp,lf)} returns \axiom{newlp}
    ++ where \axiom{newlp} is obtained from \axiom{lp} by removing
    ++ in the content of every polynomial of \axiom{lp} any non trivial
    ++ factor of any polynomial \axiom{f} in \axiom{lf}. Moreover,
    ++ squares over \axiom{R} are first removed in the content
    ++ of every polynomial of \axiom{lp}.
removeRedundantFactorsInPols : (LP, LP) -> LP
    ++ \axiom{removeRedundantFactorsInPols(lp,lf)} returns \axiom{newlp}
    ++ where \axiom{newlp} is obtained from \axiom{lp} by removing
    ++ in every polynomial \axiom{p} of \axiom{lp} any non trivial
    ++ factor of any polynomial \axiom{f} in \axiom{lf}. Moreover,
    ++ squares over \axiom{R} are first removed in every
    ++ polynomial \axiom{lp}.
if (R has EuclideanDomain) and (R has CharacteristicZero)
then
    irreducibleFactors : LP -> LP
        ++ \axiom{irreducibleFactors(lp)} returns \axiom{lf} such that if
        ++ \axiom{lp} = [p1,...,pn] and \axiom{lf} = [f1,...,fm] then
        ++ \axiom{p1*p2*...*pn=0} means \axiom{f1*f2*...*fm=0}, and the \axiom{fi}
        ++ are irreducible over \axiom{R} and are pairwise distinct.
    lazyIrreducibleFactors : LP -> LP
        ++ \axiom{lazyIrreducibleFactors(lp)} returns \axiom{lf} such that if
        ++ \axiom{lp} = [p1,...,pn] and \axiom{lf} = [f1,...,fm] then
        ++ \axiom{p1*p2*...*pn=0} means \axiom{f1*f2*...*fm=0}, and the \axiom{fi}
        ++ are irreducible over \axiom{R} and are pairwise distinct.
        ++ The algorithm tries to avoid factorization into irreducible
        ++ factors as far as possible and makes previously use of gcd
        ++ techniques over \axiom{R}.
    removeIrreducibleRedundantFactors : (LP, LP) -> LP
        ++ \axiom{removeIrreducibleRedundantFactors(lp,lq)} returns the same
        ++ as \axiom{irreducibleFactors(concat(lp,lq))} assuming
        ++ that \axiom{irreducibleFactors(lp)} returns \axiom{lp}
        ++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
        ++ by some polynomial \axiom{qj} associated to \axiom{pj}.

PolynomialSquareFree examples

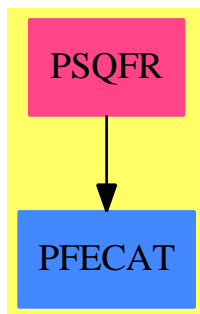

=====

This package computes square-free decomposition of multivariate polynomials over a coefficient ring which is an arbitrary gcd domain. The requirement on the coefficient domain guarantees that the content can be removed so that factors will be primitive as well as square-free. Over an infinite ring of finite characteristic, it may not be possible to guarantee that the factors are square-free.

## PrimitiveArrayFunctions2 (PRIMARR2)

**Exports:**

map reduce scan

## — package PRIMARR2 PrimitiveArrayFunctions2 —

```

)abbrev package PRIMARR2 PrimitiveArrayFunctions2
++ Description:
++ This package provides tools for operating on primitive arrays
++ with unary and binary functions involving different underlying types

PrimitiveArrayFunctions2(A, B): Exports == Implementation where
  A, B: Type

VA ==> PrimitiveArray A
VB ==> PrimitiveArray B
O2 ==> FiniteLinearAggregateFunctions2(A, VA, B, VB)
Exports ==> with
  scan : ((A, B) -> B, VA, B) -> VB
    ++ scan(f,a,r) successively applies
    ++ \spad{reduce(f,x,r)} to more and more leading sub-arrays
    ++ x of primitive array \spad{a}.
    ++ More precisely, if \spad{a} is \spad{[a1,a2,...]}, then
    ++ \spad{scan(f,a,r)} returns
    ++ \spad{[reduce(f,[a1],r),reduce(f,[a1,a2],r),...]}.
    ++
    ++X T1:=PrimitiveArrayFunctions2(Integer,Integer)
    ++X adder(a:Integer,b:Integer):Integer == a+b
    ++X scan(adder,[i for i in 1..10],0)$T1

  reduce : ((A, B) -> B, VA, B) -> B
    ++ reduce(f,a,r) applies function f to each
    ++ successive element of the
    ++ primitive array \spad{a} and an accumulant initialized to r.
    ++ For example, \spad{reduce(_+$Integer,[1,2,3],0)}
    ++ does \spad{3+(2+(1+0))}. Note that third argument r
    ++ may be regarded as the identity element for the function f.
    ++
    ++X T1:=PrimitiveArrayFunctions2(Integer,Integer)
    ++X adder(a:Integer,b:Integer):Integer == a+b
    ++X reduce(adder,[i for i in 1..10],0)$T1

  map : (A -> B, VA) -> VB
    ++ map(f,a) applies function f to each member of primitive array
    ++ \spad{a} resulting in a new primitive array over a
    ++ possibly different underlying domain.
    ++
    ++X T1:=PrimitiveArrayFunctions2(Integer,Integer)
    ++X map(x+>x+2,[i for i in 1..10])$T1

Implementation ==> add

## PrimitiveElement (PRIMELT)

### Exports:

primitiveElement

— package PRIMELT PrimitiveElement —

```

)abbrev package PRIMELT PrimitiveElement
++ Author: Manuel Bronstein
++ Date Created: 6 Jun 1990
++ Date Last Updated: 25 April 1991
++ Description:
++ PrimitiveElement provides functions to compute primitive elements
++ in algebraic extensions;

PrimitiveElement(F): Exports == Implementation where
  F : Join(Field, CharacteristicZero)

SY ==> Symbol
P ==> Polynomial F
UP ==> SparseUnivariatePolynomial F
RC ==> Record(coef1: Integer, coef2: Integer, prim:UP)
REC ==> Record(coef: List Integer, poly:List UP, prim: UP)

Exports ==> with
  primitiveElement: (P, SY, P, SY) -> RC
    ++ primitiveElement(p1, a1, p2, a2) returns \spad{[c1, c2, q]}
    ++ such that \spad{k(a1, a2) = k(a)}
    ++ where \spad{a = c1 a1 + c2 a2, and q(a) = 0}.
    ++ The pi's are the defining polynomials for the ai's.
    ++ The p2 may involve a1, but p1 must not involve a2.
    ++ This operation uses \spadfun{resultant}.
  
```

```

primitiveElement: (List P, List SY) -> REC
  ++ primitiveElement([p1,...,pn], [a1,...,an]) returns
  ++ \spad{[[c1,...,cn], [q1,...,qn], q]}
  ++ such that then \spad{k(a1,...,an) = k(a)},
  ++ where \spad{a = a1 c1 + ... + an cn},
  ++ \spad{ai = qi(a)}, and \spad{q(a) = 0}.
  ++ The pi's are the defining polynomials for the ai's.
  ++ This operation uses the technique of
  ++ \spadglossSee{groebner bases}{Groebner basis}.
primitiveElement: (List P, List SY, SY) -> REC
  ++ primitiveElement([p1,...,pn], [a1,...,an], a) returns
  ++ \spad{[[c1,...,cn], [q1,...,qn], q]}
  ++ such that then \spad{k(a1,...,an) = k(a)},
  ++ where \spad{a = a1 c1 + ... + an cn},
  ++ \spad{ai = qi(a)}, and \spad{q(a) = 0}.
  ++ The pi's are the defining polynomials for the ai's.
  ++ This operation uses the technique of
  ++ \spadglossSee{groebner bases}{Groebner basis}.

Implementation ==> add
import PolyGroebner(F)

)abbrev package ODEPRIM PrimitiveRatDE
++ Author: Manuel Bronstein
++ Date Created: 1 March 1991
++ Date Last Updated: 1 February 1994
++ Description:
++ \spad{PrimitiveRatDE} provides functions for in-field solutions of linear
++ ordinary differential equations, in the transcendental case.
++ The derivation to use is given by the parameter \spad{L}.

PrimitiveRatDE(F, UP, L, LQ): Exports == Implementation where
  F : Join(Field, CharacteristicZero, RetractableTo Fraction Integer)
  UP : UnivariatePolynomialCategory F
  L : LinearOrdinaryDifferentialOperatorCategory UP
  LQ : LinearOrdinaryDifferentialOperatorCategory Fraction UP

N ==> NonNegativeInteger
Z ==> Integer
RF ==> Fraction UP
UP2 ==> SparseUnivariatePolynomial UP
REC ==> Record(center:UP, equation:UP)

Exports ==> with
  denomLODE: (L, RF) -> Union(UP, "failed")
    ++ denomLODE(op, g) returns a polynomial d such that
    ++ any rational solution of \spad{op y = g}
    ++ is of the form \spad{p/d} for some polynomial p, and
    ++ "failed", if the equation has no rational solution.
  denomLODE: (L, List RF) -> UP
    ++ denomLODE(op, [g1,...,gm]) returns a polynomial
    ++ d such that any rational solution of \spad{op y = c1 g1 + ... + cm gm}
    ++ is of the form \spad{p/d} for some polynomial p.
  indicialEquations: L -> List REC
    ++ indicialEquations op returns \spad{[[d1,e1],...,[dq,eq]]} where
    ++ the \spad{d_i}'s are the affine singularities of \spad{op},
    ++ and the \spad{e_i}'s are the indicial equations at each \spad{d_i}.
  indicialEquations: (L, UP) -> List REC
    ++ indicialEquations(op, p) returns \spad{[[d1,e1],...,[dq,eq]]} where
    ++ the \spad{d_i}'s are the affine singularities of \spad{op}
    ++ above the roots of \spad{p},
    ++ and the \spad{e_i}'s are the indicial equations at each \spad{d_i}.

Exports ==> with
  denomRicDE: L -> UP
    ++ denomRicDE(op) returns a polynomial \spad{d} such that any rational
    ++ solution of the associated Riccati equation of \spad{op y = 0} is
    ++ of the form \spad{p/d + q'/q + r} for some polynomials p and q
    ++ and a reduced r. Also, \spad{deg(p) < deg(d)} and {gcd(d,q) = 1}.
  leadingCoefficientRicDE: L -> List REC
    ++ leadingCoefficientRicDE(op) returns
    ++ \spad{[[m1, p1], [m2, p2], ... , [mk, pk]]} such that the polynomial
    ++ part of any rational solution of the associated Riccati equation of
    ++ \spad{op y = 0} must have degree mj for some j, and its leading
    ++ coefficient is then a zero of pj. In addition, \spad{m1>m2> ... >mk}.
  constantCoefficientRicDE: (L, UP -> List F) -> List CNT
    ++ constantCoefficientRicDE(op, ric) returns
    ++ \spad{[[a1, L1], [a2, L2], ... , [ak, Lk]]} such that any rational
    ++ solution with no polynomial part of the associated Riccati equation of
    ++ \spad{op y = 0} must be one of the ai's in which case the equation for
    ++ \spad{z = y e^{-int ai}} is \spad{Li z = 0}.
    ++ \spad{ric} is a Riccati equation solver over \spad{F}, whose input
    ++ is the associated linear equation.
  polyRicDE: (L, UP -> List F) -> List POL
    ++ polyRicDE(op, zeros) returns
    ++ \spad{[[p1, L1], [p2, L2], ... , [pk, Lk]]} such that the polynomial

```

```

++ part of any rational solution of the associated Riccati equation of
++ \spad{op y=0} must be one of the pi's (up to the constant coefficient),
++ in which case the equation for \spad{z=y e^{-int p}} is \spad{Li z =0}.
++ \spad{zeros} is a zero finder in \spad{UP}.
singRicDE: (L, (UP, UP2) -> List UP, UP -> Factored UP) -> List FRC
++ singRicDE(op, zeros, ezfactor) returns
++ \spad{[[f1, L1], [f2, L2], ... , [fk, Lk]]} such that the singular
++ part of any rational solution of the associated Riccati equation of
++ \spad{op y=0} must be one of the fi's (up to the constant coefficient),
++ in which case the equation for \spad{z=y e^{-int p}} is \spad{Li z=0}.
++ \spad{zeros(C(x),H(x,y))} returns all the \spad{P_i(x)}'s such that
++ \spad{H(x,P_i(x)) = 0 modulo C(x)}.
++ Argument \spad{ezfactor} is a factorisation in \spad{UP},
++ not necessarily into irreducibles.
changeVar: (L, UP) -> L
++ changeVar(+/[ai D^i], a) returns the operator \spad{+/[ai (D+a)^i]}.
changeVar: (L, RF) -> L
++ changeVar(+/[ai D^i], a) returns the operator \spad{+/[ai (D+a)^i]}.

)abbrev package PSEUDLIN PseudoLinearNormalForm
++ Author: Bruno Zuercher
++ Date Created: November 1993
++ Date Last Updated: 12 April 1994
++ Description:
++ PseudoLinearNormalForm provides a function for computing a block-companion
++ form for pseudo-linear operators.

PseudoLinearNormalForm(K:Field): Exports == Implementation where
  ER ==> Record(C: Matrix K, g: Vector K)
  REC ==> Record(R: Matrix K, A: Matrix K, Ainv: Matrix K)

Exports ==> with
  normalForm: (Matrix K, Automorphism K, K -> K) -> REC
    ++ normalForm(M, sig, der) returns \spad{[R, A, A^{-1}]} such that
    ++ the pseudo-linear operator whose matrix in the basis \spad{y} is
    ++ \spad{M} had matrix \spad{R} in the basis \spad{z = A y}.
    ++ \spad{der} is a \spad{sig}-derivation.
  changeBase: (Matrix K, Matrix K, Automorphism K, K -> K) -> Matrix K
    ++ changeBase(M, A, sig, der): computes the new matrix of a pseudo-linear
    ++ transform given by the matrix M under the change of base A
  companionBlocks: (Matrix K, Vector K) -> List ER
    ++ companionBlocks(m, v) returns \spad{[[C_1, g_1], ..., [C_k, g_k]]}
    ++ such that each \spad{C_i} is a companion block and
    ++ \spad{m = diagonal(C_1, ..., C_k)}.

Implementation ==> add
  normalForm0: (Matrix K, Automorphism K, Automorphism K, K -> K) -> REC
  mulMatrix: (Integer, Integer, K) -> Matrix K
    -- mulMatrix(N, i, a): under a change of base with the resulting matrix of
  
```

```

-- size N*N the following operations are performed:
-- D1: column i will be multiplied by sig(a)
-- D2: row i will be multiplied by 1/a
-- D3: addition of der(a)/a to the element at position (i,i)
addMatrix: (Integer, Integer, Integer, K) -> Matrix K
-- addMatrix(N, i, k, a): under a change of base with the resulting matrix
-- of size N*N the following operations are performed:
-- C1: addition of column i multiplied by sig(a) to column k
-- C2: addition of row k multiplied by -a to row i
-- C3: addition of -a*der(a) to the element at position (i,k)
permutationMatrix: (Integer, Integer, Integer) -> Matrix K
-- permutationMatrix(N, i, k): under a change of base with the resulting
-- permutation matrix of size N*N the following operations are performed:
-- P1: columns i and k will be exchanged
-- P2: rows i and k will be exchanged
inv: Matrix K -> Matrix K
-- inv(M): computes the inverse of a invertable matrix M.
-- avoids possible type conflicts

PseudoRemainderSequence examples
=====
```

The package constructor PseudoRemainderSequence provides efficient algorithms by Lionel Ducos (University of Poitiers, France) for computing sub-resultants. This leads to a speed up in many places in Axiom where sub-resultants are computed (polynomial system solving, algebraic factorization, integration).

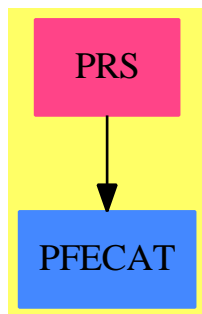

This package contains some functions from improvements of the subresultants algorithm.

++ \axiom{semiSubResultantGcdEuclidean1(P,Q)} carries out the equality
++ \axiom{coef1*P + ? Q = +/- S_i(P,Q)}
++ where the degree (not the indice)
++ of the subresultant \axiom{S_i(P,Q)} is the smaller as possible.

discriminant : polR -> R
++ \axiom{discriminant(P, Q)} returns the discriminant
++ of \axiom{P} and \axiom{Q}.

discriminantEuclidean : polR ->
    Record(coef1 : polR, coef2 : polR, discriminant : R)
++ \axiom{discriminantEuclidean(P)} carries out the equality
++ \axiom{coef1 * P + coef2 * D(P) = discriminant(P)}.

semiDiscriminantEuclidean : polR ->
    Record(coef2 : polR, discriminant : R)

```

```

++ \axiom{discriminantEuclidean(P)} carries out the equality
++ \axiom{...P + coef2 * D(P) = discriminant(P)}.
++ Warning. \axiom{degree(P) >= degree(Q)}.

chainSubResultants : (polR, polR) -> List(polR)
++ \axiom{chainSubResultants(P, Q)} computes the list
++ of non zero subresultants of \axiom{P} and \axiom{Q}.

schema : (polR, polR) -> List(NNI)
++ \axiom{schema(P,Q)} returns the list of degrees of
++ non zero subresultants of \axiom{P} and \axiom{Q}.

if R has GcdDomain then
  resultantRedit : (polR, polR) -> R
  ++ \axiom{resultantRedit(P,Q)} returns the "reduce resultant"
  ++ of \axiom{P} and \axiom{Q}.

  resultantReditEuclidean : (polR, polR) ->
    Record(coef1 : polR, coef2 : polR, resultantRedit : R)
  ++ \axiom{resultantReditEuclidean(P,Q)} returns
  ++ the "reduce resultant" and carries out the equality
  ++ \axiom{coef1*P + coef2*Q = resultantRedit(P,Q)}.

  semiResultantReditEuclidean : (polR, polR) ->
    Record(coef2 : polR, resultantRedit : R)
  ++ \axiom{semiResultantReditEuclidean(P,Q)} returns
  ++ the "reduce resultant" and carries out the equality
  ++ \axiom{...P + coef2*Q = resultantRedit(P,Q)}.

  gcd : (polR, polR) -> polR
  ++ \axiom{gcd(P, Q)} returns the gcd of \axiom{P} and \axiom{Q}.

-- sub-routines exported for convenience -----

"*" : (R, Vector(polR)) -> Vector(polR)
++ \axiom{r * v} computes the product of \axiom{r} and \axiom{v}

"exquo" : (Vector(polR), R) -> Vector(polR)
++ \axiom{v exquo r} computes
++ the exact quotient of \axiom{v} by \axiom{r}

pseudoDivide : (polR, polR) ->
  Record(coef:R, quotient:polR, remainder:polR)
++ \axiom{pseudoDivide(P,Q)} computes the pseudoDivide
++ of \axiom{P} by \axiom{Q}.

divide : (polR, polR) -> Record(quotient : polR, remainder : polR)
++ \axiom{divide(F,G)} computes quotient and rest
++ of the exact euclidean division of \axiom{F} by \axiom{G}.

```

```

Lazard : (R, R, NNI) -> R
  ++ \axiom{Lazard(x, y, n)} computes \axiom{x**n/y**(n-1)}

Lazard2 : (polR, R, R, NNI) -> polR
  ++ \axiom{Lazard2(F, x, y, n)} computes \axiom{(x/y)**(n-1) * F}

next_sousResultant2 : (polR, polR, polR, R) -> polR
  ++ \axiom{nextsousResultant2(P, Q, Z, s)} returns
  ++ the subresultant \axiom{S_{e-1}} where
  ++ \axiom{P ~ S_d, Q = S_{d-1}, Z = S_e, s = lc(S_d)}

resultant_naif : (polR, polR) -> R
  ++ \axiom{resultantEuclidean_naif(P,Q)} returns
  ++ the resultant of \axiom{P} and \axiom{Q} computed
  ++ by means of the naive algorithm.

resultantEuclidean_naif : (polR, polR) ->
  Record(coef1 : polR, coef2 : polR, resultant : R)
  ++ \axiom{resultantEuclidean_naif(P,Q)} returns
  ++ the extended resultant of \axiom{P} and \axiom{Q} computed
  ++ by means of the naive algorithm.

semiResultantEuclidean_naif : (polR, polR) ->
  Record(coef2 : polR, resultant : R)
  ++ \axiom{resultantEuclidean_naif(P,Q)} returns
  ++ the semi-extended resultant of \axiom{P} and \axiom{Q} computed
  ++ by means of the naive algorithm.

U3 ==> Union(Record(mainpart:F, limitedlogs:List LOG), "failed")
FAIL==> error "failed - cannot handle that integrand"

Exports ==> with
  palgint : (F, K, K) -> IR
  ++ palgint(f, x, y) returns the integral of \spad{f(x,y)dx}
  ++ where y is an algebraic function of x.
  palgextint: (F, K, K, F) -> U2
  ++ palgextint(f, x, y, g) returns functions \spad{[h, c]} such that
  ++ \spad{dh/dx = f(x,y) - c g}, where y is an algebraic function of x;
  ++ returns "failed" if no such functions exist.
  palglimint: (F, K, K, List F) -> U3
  ++ palglimint(f, x, y, [u1,...,un]) returns functions
  ++ \spad{[h,[[ci, ui]]]} such that the ui's are among \spad{[u1,...,un]}
  ++ and \spad{d(h + sum(ci log(ui)))/dx = f(x,y)} if such functions exist,
  ++ "failed" otherwise;
  ++ y is an algebraic function of x.
  palgrDE : (F, F, F, K, K, (F, F, SY) -> U1) -> U1
  ++ palgrDE(nfp, f, g, x, y, foo) returns a function \spad{z(x,y)}
  ++ such that \spad{dz/dx + n * df/dx z(x,y) = g(x,y)} if such a z exists,
  ++ "failed" otherwise;
  ++ y is an algebraic function of x;
  ++ \spad{foo(a, b, x)} is a function that solves
  ++ \spad{du/dx + n * da/dx u(x) = u(x)}
  ++ for an unknown \spad{u(x)} not involving y.
  ++ \spad{nfp} is \spad{n * df/dx}.
  if L has LinearOrdinaryDifferentialOperatorCategory F then
    palgLODE: (L, F, K, K, SY) -> REC
    ++ palgLODE(op, g, kx, y, x) returns the solution of \spad{op f = g}.
    ++ y is an algebraic function of x.

=====
QuasiAlgebraicSet2 examples
=====
```

QuasiAlgebraicSet2 adds a function `radicalSimplify` which uses `IdealDecompositionPackage` to simplify the representation of a quasi-algebraic set.

A quasi-algebraic set is the intersection of a Zariski closed set, defined as the common zeros of a given list of polynomials (the defining polynomials for equations), and a principal Zariski open set, defined as the complement of the common zeros of a polynomial  $f$  (the defining polynomial for the inequation).

Quasi-algebraic sets are implemented in the domain `QuasiAlgebraicSet`, where two simplification routines are provided: `idealSimplify` and `simplify`.

The function `radicalSimplify` is added for comparison study only.

Because the domain `IdealDecompositionPackage` provides facilities for computing with radical ideals, it is necessary to restrict the ground ring to the domain `Fraction Integer`, and the polynomial ring to be of type `DistributedMultivariatePolynomial`.

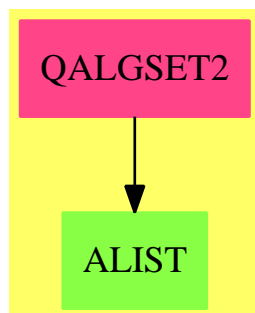

The routine `radicalSimplify` uses these to compute groebner basis of radical ideals and is inefficient and restricted when compared to the two in `QuasiAlgebraicSet`.

— QuaternionCategoryFunctions2.help —

QuaternionCategoryFunctions2 implements functions between two quaternion domains. The function map is used by the system interpreter to coerce between quaternion types.

The package QuaternionCategoryFunctions2 provides a function map to convert an expression in Quaternion(R) to an expression in Quaternion(S) using the function f.

$$\frac{2}{11} - 8i + \frac{3}{4}j + k$$

Type: Quaternion Fraction Integer

```
f(a:Fraction Integer):Complex Fraction Integer == a::Complex Fraction Integer
Function declaration f : Fraction Integer -> Complex Fraction
Integer has been added to workspace.
```

Type: Void

```
map(f,q)
Compiling function f with type Fraction Integer -> Complex Fraction
Integer
```

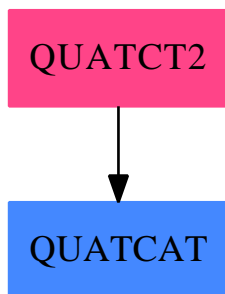

$$-- - 8i + \frac{2}{11} - \frac{3}{4}j + k$$

Type: Quaternion Complex Fraction Integer

 radicalEigenvalues   radicalEigenvectors

— package REP RadicalEigenPackage —

```

)abbrev package REP RadicalEigenPackage
++ Author: P.Gianni
++ Date Created: Summer 1987
++ Date Last Updated: October 1992
++ Description:
++ Package for the computation of eigenvalues and eigenvectors.
++ This package works for matrices with coefficients which are
++ rational functions over the integers.
++ (see \spadtype{Fraction Polynomial Integer}).
++ The eigenvalues and eigenvectors are expressed in terms of radicals.
  
```

```

RadicalEigenPackage() : C == T
where
  R    ==> Integer
  P    ==> Polynomial R
  F    ==> Fraction P
  RE   ==> Expression R
  SE   ==> Symbol()
  
```

```

M      ==> Matrix(F)
MRE    ==> Matrix(RE)
ST      ==> SuchThat(SE,P)
NNI     ==> NonNegativeInteger

EigenForm    ==> Record(eigval:Union(F,ST),eigmult:NNI,eigvec:List(M))
RadicalForm  ==> Record(radval:RE,radmult:Integer,radvect:List(MRE))

C == with
  radicalEigenvectors      : M      -> List(RadicalForm)
    ++ radicalEigenvectors(m) computes
    ++ the eigenvalues and the corresponding eigenvectors of the
    ++ matrix m;
    ++ when possible, values are expressed in terms of radicals.

  radicalEigenvector      : (RE,M)   -> List(MRE)
    ++ radicalEigenvector(c,m) computes the eigenvector(s) of the
    ++ matrix m corresponding to the eigenvalue c;
    ++ when possible, values are
    ++ expressed in terms of radicals.

  radicalEigenvalues      : M      -> List RE
    ++ radicalEigenvalues(m) computes the eigenvalues of the matrix m;
    ++ when possible, the eigenvalues are expressed in terms of radicals.

  eigenMatrix             : M      -> Union(MRE,"failed")
    ++ eigenMatrix(m) returns the matrix b
    ++ such that \spad{b*m*(inverse b)} is diagonal,
    ++ or "failed" if no such b exists.

  normalise               : MRE     -> MRE
    ++ normalise(v) returns the column
    ++ vector v
    ++ divided by its euclidean norm;
    ++ when possible, the vector v is expressed in terms of radicals.

  gramschmidt             : List(MRE) -> List(MRE)
    ++ gramschmidt(lv) converts the list of column vectors lv into
    ++ a set of orthogonal column vectors
    ++ of euclidean length 1 using the Gram-Schmidt algorithm.

  orthonormalBasis        : M      -> List(MRE)
    ++ orthonormalBasis(m) returns the orthogonal matrix b such that
    ++ \spad{b*m*(inverse b)} is diagonal.
    ++ Error: if m is not a symmetric matrix.

T == add
  PI      ==> PositiveInteger

=====
RadicalSolvePackage examples
=====
```

This package tries to find solutions expressed in terms of radicals for systems of equations of rational functions with coefficients in an integral domain R.

```
b:Fraction(Polynomial(Integer)):= (3*x^3+7)/(5*x^2-13)
```

$$\frac{3x^3 + 7}{5x^2 - 13}$$

```
radicalSolve(b,x)
```

$$\left[ x = \frac{\sqrt[3]{-7} \sqrt[3]{-7} \sqrt[3]{-1} \sqrt[3]{13} - \sqrt[3]{-7}}{\sqrt[3]{3}}, x = \frac{\sqrt[3]{-7} \sqrt[3]{-7} \sqrt[3]{-1} \sqrt[3]{13} - \sqrt[3]{-7}}{2\sqrt[3]{13}}, x = \frac{\sqrt[3]{-7} \sqrt[3]{-7} \sqrt[3]{-1} \sqrt[3]{13} - \sqrt[3]{-7}}{2\sqrt[3]{13}} \right]$$

```
radicalSolve(b)
```

$$\left[ x = \frac{\sqrt[3]{-7} \sqrt[3]{-7} \sqrt[3]{-1} \sqrt[3]{13} - \sqrt[3]{-7}}{\sqrt[3]{3}}, x = \frac{\sqrt[3]{-7} \sqrt[3]{-7} \sqrt[3]{-1} \sqrt[3]{13} - \sqrt[3]{-7}}{2\sqrt[3]{13}}, x = \frac{\sqrt[3]{-7} \sqrt[3]{-7} \sqrt[3]{-1} \sqrt[3]{13} - \sqrt[3]{-7}}{2\sqrt[3]{13}} \right]$$

```
radicalSolve(b=0,x)
```

$$\left[ x = \frac{\sqrt[3]{-7} \sqrt[3]{-7} \sqrt[3]{-1} \sqrt[3]{13} - \sqrt[3]{-7}}{\sqrt[3]{3}}, x = \frac{\sqrt[3]{-7} \sqrt[3]{-7} \sqrt[3]{-1} \sqrt[3]{13} - \sqrt[3]{-7}}{2\sqrt[3]{13}}, x = \frac{\sqrt[3]{-7} \sqrt[3]{-7} \sqrt[3]{-1} \sqrt[3]{13} - \sqrt[3]{-7}}{2\sqrt[3]{13}} \right]$$

```

RationalFactorize examples

=====

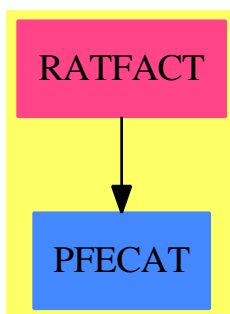

Factorization of extended polynomials with rational coefficients. This package implements factorization of extended polynomials whose coefficients are rational numbers. It does this by taking the lcm of the coefficients of the polynomial and creating a polynomial with integer coefficients. The algorithm in GaloisGroupFactorizer is then used to factor the integer polynomial. The result is normalized with respect to the original lcm of the denominators.

— RationalFunctionSum.help —

```
=====
RationalFunctionSum examples
=====
```

Computes sums of rational functions.

There are 4 different forms of the sum operator in this domain.  
They are variations of the types of the input

```
sum(i::Polynomial(Integer),variable(i=1..n))
```

$$\frac{6i^2 - 6i + 1}{12}$$

```
sum(i::Fraction(Polynomial(Integer)),i::Symbol)
```

$$\frac{6i^2 - 6i + 1}{12}$$

```
sum(i,i=1..n)
```

$$\frac{n^2 + n}{2}$$

```
sum(i::Fraction(Polynomial(Integer)),i=1..n)
```

$$\frac{n^2 + n}{2}$$

We can compute the sum form on part at a time to see what happens.  
First, we make a SegmentBinding(Polynomial(Integer)):

```
s:=i=1..n
```

```
i= 1..n
```

We pick out the upper and lower bounds of the segment:

```
hiseg:=high(segment(s))
```

```
n
```

```
loseg:=low(segment(s))
```

```
1
```

We pick out the variable from the segment:

```
v:=variable s
```

```
i
```

We create a polynomial we wish to sum:

```
p:=i::Polynomial(Integer)
```

```
i
```

And we create the sum for that polynomial:

```
f:=sum(p,v)
```

$$6i^2 - 6i + 1$$

$$\frac{\quad}{12}$$

The new evaluate it at the upper endpoint:

```
t1:=eval(f,v,(1+hiseg))
```

$$\frac{6n^2 + 6n + 1}{12}$$

And the lower endpoint:

```
t2:=eval(f,v,loseg)
```

$$\frac{1}{12}$$

And we take the difference of the endpoints:

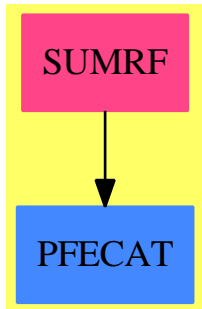

```
t1-t2
```

$$\frac{n^2 + n}{2}$$

## package RINTERP RationalInterpolation

### Introduction

This file contains a crude naïve implementation of rational interpolation, where the coefficients of the rational function are in any given field.

### Questions and Outlook

- Maybe this file should be joined with `pinterp.spad`, where polynomial Lagrange interpolation is implemented. I have a second version that parallels the structure of `pinterp.spad` closely.
- There are probably better ways to implement rational interpolation. Maybe <http://www.cs.ucsb.edu/~omer/pers> contains something useful, but I don't know.
- Comments welcome!

## RationalInterpolation (RINTERP)

### Exports:

interpolate

— package RINTERP RationalInterpolation —

```

)abbrev package RINTERP RationalInterpolation
++ Description:
++ This package exports rational interpolation algorithms

RationalInterpolation(xx,F): Exports == Implementation where
  xx: Symbol
  F: Field
  Exports == with
    interpolate: (List F, List F, NonNegativeInteger,
                  NonNegativeInteger) -> Fraction Polynomial F
  
```

—

The implementation sets up a system of linear equations and solves it.

— package RINTERP RationalInterpolation —

```

Implementation == add
  interpolate(xlist, ylist, m, k) ==
  
```

—

First we check whether we have the right number of points and values. Clearly the number of points and the number of values must be identical. Note that we want to determine the numerator and denominator polynomials only up to a factor. Thus, we want to determine

$m + k + 1$  coefficients, where  $m$  is the degree of the polynomial in the numerator and  $k$  is the degree of the polynomial in the denominator.

In fact, we could also leave – for example –  $k$  unspecified and determine it as `k=#xlist-m-1`: I don't know whether this would be better.

— **package RINTERP RationalInterpolation** —

```
#xlist ^= #ylist =>
  error "Different number of points and values."
#xlist ^= m+k+1 =>
  error "wrong number of points"
```

—————

The next step is to set up the matrix. Suppose that our numerator polynomial is  $p(x) = a_0 + a_1x + \dots + a_mx^m$  and that our denominator polynomial is  $q(x) = b_0 + b_1x + \dots + b_kx^k$ . Then we have the following equations, writing  $n$  for  $m + k + 1$ :

$$\begin{aligned} p(x_1) - y_1q(x_1) &= a_0 + a_1x_1 + \dots + a_mx_1^m - y_1(b_0 + b_1x_1 + \dots + b_kx_1^k) = 0 \\ p(x_2) - y_2q(x_2) &= a_0 + a_1x_2 + \dots + a_mx_2^m - y_2(b_0 + b_1x_2 + \dots + b_kx_2^k) = 0 \\ &\vdots \\ p(x_n) - y_nq(x_n) &= a_0 + a_1x_n + \dots + a_mx_n^m - y_n(b_0 + b_1x_n + \dots + b_kx_n^k) = 0 \end{aligned}$$

This can be written as

$$\begin{bmatrix} 1 & x_1 & \dots & x_1^m & -y_1 & -y_1x_1 & \dots & -y_1x_1^k \\ 1 & x_2 & \dots & x_2^m & -y_2 & -y_2x_2 & \dots & -y_2x_2^k \\ & & & \vdots & & & & \\ 1 & x_n & \dots & x_n^m & -y_n & -y_nx_n & \dots & -y_nx_n^k \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ \vdots \\ a_m \\ b_0 \\ b_1 \\ \vdots \\ b_k \end{bmatrix} = 0$$

We generate this matrix columnwise:

— **package RINTERP RationalInterpolation** —

```
tempvec: List F := [1 for i in 1..(m+k+1)]

collist: List List F := cons(tempvec,
  [(tempvec := [tempvec.i * xlist.i _
    for i in 1..(m+k+1)]) _
  for j in 1..max(m,k)])

collist := append([collist.j for j in 1..(m+1)], _
  [[- collist.j.i * ylist.i for i in 1..(m+k+1)] _
  for j in 1..(k+1)])
```

---

Now we can solve the system:

— **package RINTERP RationalInterpolation** —

```
res: List Vector F := nullSpace((transpose matrix collist) _
                                ::Matrix F)
```

---

Note that it may happen that the system has several solutions. In this case, some of the data points may not be interpolated correctly. However, the solution is often still useful, thus we do not signal an error.

— **package RINTERP RationalInterpolation** —

```
if #res~=1 then output("Warning: unattainable points!" _
                      ::OutputForm)$OutputPackage
```

---

In this situation, all the solutions will be equivalent, thus we can always simply take the first one:

— **package RINTERP RationalInterpolation** —

```
reslist: List List Polynomial F := _
  [[(res.1).(i+1)*(xx::Polynomial F)**i for i in 0..m], _
   [(res.1).(i+m+2)*(xx::Polynomial F)**i for i in 0..k]]
```

---

Finally, we generate the rational function:

— **package RINTERP RationalInterpolation** —

```
reduce((_+),reslist.1)/reduce((_+),reslist.2)
```

---

— **RINTERP.dotabb** —

```
"RINTERP" [color="#FF4488",href="bookvol10.4.pdf#nameddest=RINTERP"]
"PFECAT" [color="#4488FF",href="bookvol10.2.pdf#nameddest=PFECAT"]
"RINTERP" -> "PFECAT"
```

Exports == with

rur: (LP,Boolean) -> List RUR
++ \spad{rur(lp,univ?) returns a rational univariate representation
++ of \spad{lp}. This assumes that \spad{lp} defines a regular
++ triangular \spad{ts} whose associated variety is zero-dimensional
++ over \spad{R}. \spad{rur(lp,univ?) returns a list of items
++ \spad{[u,lc]} where \spad{u} is an irreducible univariate polynomial
++ and each \spad{c} in \spad{lc} involves two variables: one from \spad{ls},
++ called the coordinate of \spad{c}, and an extra variable which
++ represents any root of \spad{u}. Every root of \spad{u} leads to
++ a tuple of values for the coordinates of \spad{lc}. Moreover,
++ a point \spad{x} belongs to the variety associated with \spad{lp} iff
++ there exists an item \spad{[u,lc]} in \spad{rur(lp,univ?) and
++ a root \spad{r} of \spad{u} such that \spad{x} is given by the
++ tuple of values for the coordinates of \spad{lc} evaluated at \spad{r}.
++ If \spad{univ?} is \spad{true} then each polynomial \spad{c}
++ will have a constant leading coefficient w.r.t. its coordinate.
++ See the example which illustrates the \spadtype{ZeroDimensionalSolvePackage}
++ package constructor.
rur: (LP) -> List RUR
++ \spad{rur(lp)} returns the same as \spad{rur(lp,true)}
rur: (LP,Boolean,Boolean) -> List RUR
++ \spad{rur(lp,univ?,check?) returns the same as \spad{rur(lp,true)}.
++ Moreover, if \spad{check?} is \spad{true} then the result is checked.

## package POLUTIL RealPolynomialUtilitiesPackage

This file describes the Real Closure 1.0 package which consists of different packages, categories and domains.

The package RealPolynomialUtilitiesPackage which receives a field and a univariate polynomial domain with coefficients in the field. It computes some simple functions such as Strum and Sylvester sequences.

The category RealRootCharacterizationCategory provides abstract functionalities to work with "real roots" of univariate polynomials. These resemble variables with some functionalities needed to compute important operations.

RealClosedField is a category with provides common operations available over real closed fields. These include finding all the roots of univariate polynomial, taking square roots, ...

### CAVEATS

Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any new algebraic takes precedence over older ones. In particular every creation function raises a new "real root". This has the effect that when you type something like  $\sqrt{2} + \sqrt{2}$  you have two new variables which happen to be equal. To avoid this name the expression such as in  $s2 := \sqrt{2} ; s2 + s2$

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which most natural to you.

### LIMITATIONS

The file reclos.input show some basic use of the package. This packages uses algorithms which are published in [1] and [2] which are based on field arithmetics, in particular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Beta versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done exactly. They can thus be quite time consuming when depending on several “real roots”.

Exports == with

evalRec: (BasicOperator, Symbol, F, F, F, List F) -> F
  ++ \spad{evalRec(u, dummy, n, n0, eq, values)} creates an expression that
  ++ stands for  $u(n_0)$ , where  $u(n)$  is given by the equation eq. However, for
  ++ technical reasons the variable  $n$  has to be replaced by a dummy
  ++ variable dummy in eq. The argument values specifies the initial values
  ++ of the recurrence  $u(0), u(1), \dots$ 
  ++ For the moment we don't allow recursions that contain  $u$  inside of
  ++ another operator.

evalADE: (BasicOperator, Symbol, F, F, F, List F) -> F
  ++ \spad{evalADE(f, dummy, x, n, eq, values)} creates an expression that
  ++ stands for the coefficient of  $x^n$  in the Taylor expansion of  $f(x)$ ,
  ++ where  $f(x)$  is given by the functional equation eq. However, for
  ++ technical reasons the variable  $x$  has to be replaced by a dummy
  ++ variable dummy in eq. The argument values specifies the first few
  ++ Taylor coefficients.

getEq: F -> F
  ++ \spad{getEq f} returns the defining equation, if  $f$  represents the
  ++ coefficient of an ADE or a recurrence.

getOp: F -> BasicOperator
  ++ \spad{getOp f}, if  $f$  represents the coefficient of a recurrence or
  ++ ADE, returns the operator representing the solution

        ker: Kernel F)

```

```
Implementation == add
\getchunk{implementation: RecurrenceOperator}
```

---

## Defining new operators

We define two new operators, one for recurrences, the other for functional equations. The operators for recurrences represents the  $n^{\text{th}}$  term of the corresponding sequence, the other the coefficient of  $x^n$  in the Taylor series expansion.

### — implementation: RecurrenceOperator —

```
oprecur := operator("rootOfRec"::Symbol)$BasicOperator
opADE := operator("rootOfADE"::Symbol)$BasicOperator

setProperty(oprecur, "%dummyVar", 2 pretend None)
setProperty(opADE, "%dummyVar", 2 pretend None)
```

---

Setting these properties implies that the second and third arguments of `oprecur` are dummy variables and affects `tower$ES`: the second argument will not appear in `tower$ES`, if it does not appear in any argument but the first and second. The third argument will not appear in `tower$ES`, if it does not appear in any other argument. (`%defsum` is a good example)

The arguments of the two operators are as follows:

1. eq, i.e. the vanishing expression

### — implementation: RecurrenceOperator —

```
eqAsF: List F -> F
eqAsF 1 == 1.1
```

---

2. dummy, a dummy variable to make substitutions possible

### — implementation: RecurrenceOperator —

```
dummy: List F -> Symbol
dummy 1 == retract(1.2)$Symbol

dummyAsF: List F -> F
dummyAsF 1 == 1.2
```

---

3. the variable for display

— **implementation: RecurrenceOperator** —

```
displayVariable: List F -> F
displayVariable 1 == 1.3
```

---

4. operatorName(argument)

— **implementation: RecurrenceOperator** —

```
operatorName: List F -> BasicOperator
operatorName 1 == operator(kernels(1.4).1)

operatorNameAsF: List F -> F
operatorNameAsF 1 == 1.4

operatorArgument: List F -> F
operatorArgument 1 == argument(kernels(1.4).1).1
```

---

Concerning rootOfADE, note that although we have arg as argument of the operator, it is intended to indicate the coefficient, not the argument of the power series.

5. values in reversed order.

- rootOfRec: maybe values should be preceded by the index of the first given value. Currently, the last value is interpreted as  $f(0)$ .
- rootOfADE: values are the first few coefficients of the power series expansion in order.

— **implementation: RecurrenceOperator** —

```
initialValues: List F -> List F
initialValues 1 == rest(1, 4)
```

---

## Recurrences

### Extracting some information from the recurrence

We need to find out whether we can determine the next term of the sequence, and how many initial values are necessary.

#### — implementation: RecurrenceOperator —

```

if R has Ring then
  getShiftRec(op: BasicOperator, f: Kernel F, n: Symbol)
    : Union(Integer, "failed") ==
    a := argument f
    if every?(z +-> freeOf?(z, n::F), a) then return 0

    if #a ~= 1 then error "RECOP: operator should have only one argument"

    p := univariate(a.1, retract(n::F)@Kernel(F))
    if denominator p ~= 1 then return "failed"

    num := numer p

    if degree num = 1 and coefficient(num, 1) = 1
      and every?(z +-> freeOf?(z, n::F), coefficients num)
    then return retractIfCan(coefficient(num, 0))
    else return "failed"

-- if the recurrence is of the form
-- $p(n, f(n+m-o), f(n+m-o+1), \dots, f(n+m)) = 0$
-- in which case shiftInfoRec returns [m, o, f(n+m)].

  shiftInfoRec(op: BasicOperator, argsym: Symbol, eq: F):
    Record(max: Union(Integer, "failed"),
      ord: Union(Integer, "failed"),
      ker: Kernel F) ==

-- ord and ker are valid only if all shifts are Integers
-- ker is the kernel of the maximal shift.
  maxShift: Integer
  minShift: Integer
  nextKernel: Kernel F

-- We consider only those kernels that have op as operator. If there is none,
-- we raise an error. For the moment we don't allow recursions that contain op
-- inside of another operator.

  error? := true

  for f in kernels eq repeat

```

```

if is?(f, op) then
  shift := getShiftRec(op, f, argsym)
  if error? then
    error? := false
    nextKernel := f
    if shift case Integer then
      maxShift := shift
      minShift := shift
    else return ["failed", "failed", nextKernel]
  else
    if shift case Integer then
      if maxShift < shift then
        maxShift := shift

    op: BasicOperator, argsym: Symbol, eq: F): Integer ==
    numberOfValues

```

---

### Setting the evaluation property of oprecur

irecur is just a wrapper that allows us to write a recurrence relation as an operator.

— implementation: RecurrenceOperator —

```
irecur: List F -> F
irecur l ==
  evalRec(operatorName l,
    dummy l, displayVariable l,
    operatorArgument l, eqAsF l, initialValues l)

evaluate(oprecur, irecur)$BasicOperatorFunctions1(F)
```

—————

### Displaying a recurrence relation

— implementation: RecurrenceOperator —

```
ddrec: List F -> OutputForm
ddrec l ==
  op := operatorName l
  values := reverse l
  eq := eqAsF l

  numberOfValues := numberOfValuesNeeded(#values-4, op, dummy l, eq)

  vals: List OutputForm
  := cons(eval(eq, dummyAsF l, displayVariable l)::OutputForm = _
    0::OutputForm,
    [elt(op::OutputForm, [(i-1)::OutputForm]) = _
      (values.i)::OutputForm
      for i in 1..numberOfValues])

  bracket(hconcat([(operatorNameAsF l)::OutputForm,
    ": ",
    commaSeparate vals])))

setProperty(oprecur, "%specialDisp",
  ddrec@(List F -> OutputForm) pretend None)
```

—————

## Functional Equations

### Determining the number of initial values for ADE's

We use Joris van der Hoeven's instructions for ADE's. Given  $Q = p(f, f', \dots, f^{(r)})$  we first need to differentiate  $Q$  with respect to  $f^{(i)}$  for  $i \in \{0, 1, \dots, r\}$ , plug in the given truncated power series solution and determine the valuation.

— NOTYET implementation: RecurrenceOperator —

```
getValuation(op, argsym, eq, maxorder, values): Integer ==
  max: Integer := -1;
  ker: Kernel F
  for i in 0..maxorder repeat
    ker := D(op(argsym), argsym, i)::Kernel F
    pol := univariate(eq, ker)
    dif := D pol
    ground numer(dif.D(op(argsym), argsym, i))
```

---

### Extracting some information from the functional equation

getOrder returns the maximum derivative of op occurring in f.

— implementation: RecurrenceOperator —

```
getOrder(op: BasicOperator, f: Kernel F): NonNegativeInteger ==
  res: NonNegativeInteger := 0
  g := f
  while is?(g, %diff) repeat
    g := kernels(argument(g).1).1
    res := res+1

  if is?(g, op) then res else 0
```

---

### Extracting a coefficient given a functional equation

— implementation: RecurrenceOperator —

```
evalADE(op, argsym, argdisp, arg, eq, values) ==
  if not freeOf?(eq, retract(argdisp)@Symbol)
```

```

=====
RegularSetDecompositionPackage examples
=====
```

A package providing a new algorithm for solving polynomial systems by means of regular chains. Two ways of solving are proposed: in the sense of Zariski closure (like in Kalkbrener's algorithm) or in the sense of the regular zeros (like in Wu, Wang or Lazard methods). This algorithm is valid for any type of regular set. It does not care about the way a polynomial is added in an regular set, or how two quasi-components are compared (by an inclusion-test), or how the invertibility test is made in the tower of simple extensions associated with a regular set.

These operations are realized respectively by the domain TS and the packages QCMACK(R,E,V,P,TS) and RSETGCD(R,E,V,P,TS).

The same way it does not care about the way univariate polynomial gcd (with coefficients in the tower of simple extensions associated with a regular set) are computed. The only requirement is that these gcd need to have invertible initials (normalized or not).

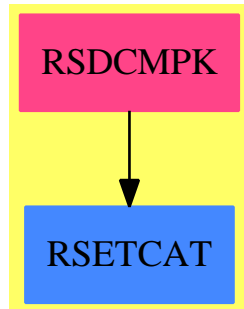

WARNING. There is no need for a user to call directly any operation of this package since they can be accessed by the domain TS. Thus, the operations of this package are not documented.

RepeatedSquaring examples
=====
```

This code computes  $x^n$  by repeated squaring. It takes advantage of the law of exponents so that if  $n=a*b$  then

$$x^n = x^a x^b$$

It also takes advantage of the fact that  $n$  has a binary representation so that a one-bit right-shift of a number divides it by 2. Thus we get three cases:

```
n = 1  -> x^1
n odd  -> repeatedsquare(x*x,n/2)*x
n even -> repeatedsquare(x*x,n/2)
```

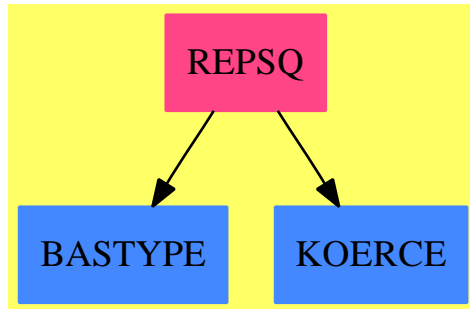

Since each recursive call divides  $n$  by 2 the algorithm is  $O(\log(n))$ .

RepresentationPackage1 examples
=====
```

RepresentationPackage1 provides functions for representation theory for finite groups and algebras.

The package creates permutation representations and uses tensor products and its symmetric and antisymmetric components to create new representations of larger degree from given ones.

Note that instead of having parameters from Permutation this package

allows list notation of permutations as well: e.g. [1,4,3,2] denotes  
permutes 2 and 4 and fixes 1 and 3.

RepresentationPackage2 provides functions for working with modular representations of finite groups and algebra. The routines in this package are created, using ideas of R. Parker, (the meat-Axe) to get smaller representations from bigger ones, i.e. finding sub- and factormodules, or to show, that such the

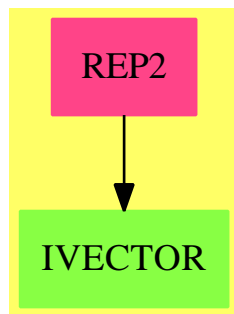

representations are irreducible.

Note that most functions are randomized functions of Las Vegas type  
i.e. every answer is correct, but with small probability  
the algorithm fails to get an answer.

```

completeEchelonBasis : V V R -> M R
  ++ completeEchelonBasis(lv) completes the basis lv assumed
  ++ to be in echelon form of a subspace of R**n (n the length
  ++ of all the vectors in lv with unit vectors to a basis of
  ++ R**n. It is assumed that the argument is not an empty
  ++ vector and that it is not the basis of the 0-subspace.
  ++ Note that the rows of the result correspond to the vectors
  ++ of the basis.
createRandomElement : (L M R, M R) -> M R
  ++ createRandomElement(aG,x) creates a random element of the group
  ++ algebra generated by aG.
-- randomWord : (L L I, L M) -> M R
  --++ You can create your own 'random' matrix with "randomWord(lli, lm)".
  --++ Each li in lli determines a product of matrices, the entries in li
  --++ determine which matrix from lm is chosen. Finally we sum over all
  --++ products. The result "sm" can be used to call split with (e.g.)
  --++ second parameter "first nullSpace sm"
if R has EuclideanDomain then -- using rowEchelon
cyclicSubmodule : (L M R, V R) -> V V R
  ++ cyclicSubmodule(lm,v) generates a basis as follows.
  ++ It is assumed that the size n of the vector equals the number
  ++ of rows and columns of the matrices. Then the matrices generate
  ++ a subalgebra, say \spad{A}, of the algebra of all square matrices of
  ++ dimension n. V R is an \spad{A}-module in the natural way.

```

```

++ cyclicSubmodule(lm,v) generates the R-Basis of Av as
++ described in section 6 of R. A. Parker's "The Meat-Axe".
++ Note that in contrast to the description in "The Meat-Axe" and to
++ standardBasisOfCyclicSubmodule the result is in echelon form.
standardBasisOfCyclicSubmodule : (L M R, V R) -> M R
++ standardBasisOfCyclicSubmodule(lm,v) returns a matrix as follows.
++ It is assumed that the size n of the vector equals the number
++ of rows and columns of the matrices. Then the matrices generate
++ a subalgebra, say \spad{A},
++ of the algebra of all square matrices of
++ dimension n. V R is an \spad{A}-module in the natural way.
++ standardBasisOfCyclicSubmodule(lm,v) calculates a matrix whose
++ non-zero column vectors are the R-Basis of Av achieved
++ in the way as described in section 6
++ of R. A. Parker's "The Meat-Axe".
++ Note that in contrast to cyclicSubmodule, the result is not
++ in echelon form.
if R has Field then -- only because of inverse in SM
areEquivalent? : (L M R, L M R, B, I) -> M R
++ areEquivalent?(aG0,aG1,randomelements,numberOfTries) tests
++ whether the two lists of matrices, all assumed of same
++ square shape, can be simultaneously conjugated by a non-singular
++ matrix. If these matrices represent the same group generators,
++ the representations are equivalent.
++ The algorithm tries
++ numberOfTries times to create elements in the
++ generated algebras in the same fashion. If their ranks differ,
++ they are not equivalent. If an
++ isomorphism is assumed, then
++ the kernel of an element of the first algebra
++ is mapped to the kernel of the corresponding element in the
++ second algebra. Now consider the one-dimensional ones.
++ If they generate the whole space (e.g. irreducibility !)
++ we use standardBasisOfCyclicSubmodule to create the
++ only possible transition matrix. The method checks whether the
++ matrix conjugates all corresponding matrices from aGi.
++ The way to choose the singular matrices is as in meatAxe.
++ If the two representations are equivalent, this routine
++ returns the transformation matrix TM with
++ aG0.i * TM = TM * aG1.i for all i. If the representations
++ are not equivalent, a small 0-matrix is returned.
++ Note that the case
++ with different sets of group generators cannot be handled.
areEquivalent? : (L M R, L M R) -> M R
++ areEquivalent?(aG0,aG1) calls areEquivalent?(aG0,aG1,true,25).
++ Note that the choice of 25 was rather arbitrary.
areEquivalent? : (L M R, L M R, I) -> M R
++ areEquivalent?(aG0,aG1,numberOfTries) calls
++ areEquivalent?(aG0,aG1,true,25).
++ Note that the choice of 25 was rather arbitrary.

```

```

isAbsolutelyIrreducible? : (L M R, I) -> B
++ isAbsolutelyIrreducible?(aG, numberOfTries) uses
++ Norton's irreducibility test to check for absolute
++ irreducibility, assuming if a one-dimensional kernel is found.
++ As no field extension changes create "new" elements
++ in a one-dimensional space, the criterium stays true
++ for every extension. The method looks for one-dimensionals only
++ by creating random elements (no fingerprints) since
++ a run of meatAxe would have proved absolute irreducibility
++ anyway.
isAbsolutelyIrreducible? : L M R -> B
++ isAbsolutelyIrreducible?(aG) calls
++ isAbsolutelyIrreducible?(aG,25).
++ Note that the choice of 25 was rather arbitrary.
split : (L M R, V R) -> L L M R
++ split(aG, vector) returns a subalgebra \spad{A} of all
++ square matrix of dimension n as a list of list of matrices,
++ generated by the list of matrices aG, where n denotes both
++ the size of vector as well as the dimension of each of the
++ square matrices.
++ V R is an A-module in the natural way.
++ split(aG, vector) then checks whether the cyclic submodule
++ generated by vector is a proper submodule of V R.
++ If successful, it returns a two-element list, which contains
++ first the list of the representations of the submodule,
++ then the list of the representations of the factor module.
++ If the vector generates the whole module, a one-element list
++ of the old representation is given.
++ Note that a later version this should call the other split.
split: (L M R, V V R) -> L L M R
++ split(aG,submodule) uses a proper submodule of R**n
++ to create the representations of the submodule and of
++ the factor module.
if (R has Finite) and (R has Field) then
meatAxe : (L M R, B, I, I) -> L L M R
++ meatAxe(aG,randomElements,numberOfTries, maxTests) returns
++ a 2-list of representations as follows.
++ All matrices of argument aG are assumed to be square
++ and of equal size.
++ Then \spad{aG} generates a subalgebra, say \spad{A}, of the algebra
++ of all square matrices of dimension n. V R is an A-module
++ in the usual way.
++ meatAxe(aG,numberOfTries, maxTests) creates at most
++ numberOfTries random elements of the algebra, tests
++ them for singularity. If singular, it tries at most maxTests
++ elements of its kernel to generate a proper submodule.
++ If successful, a 2-list is returned: first, a list
++ containing first the list of the
++ representations of the submodule, then a list of the
++ representations of the factor module.

```

```

++ Otherwise, if we know that all the kernel is already
++ scanned, Norton's irreducibility test can be used either
++ to prove irreducibility or to find the splitting.
++ If randomElements is false, the first 6 tries
++ use Parker's fingerprints.
meatAxe : L M R -> L L M R
++ meatAxe(aG) calls meatAxe(aG,false,25,7) returns
++ a 2-list of representations as follows.
++ All matrices of argument \spad{aG} are assumed to be square
++ and of
++ equal size. Then \spad{aG} generates a subalgebra,
++ say \spad{A}, of the algebra
++ of all square matrices of dimension n. V R is an A-module
++ in the usual way.
++ meatAxe(aG) creates at most 25 random elements
++ of the algebra, tests
++ them for singularity. If singular, it tries at most 7
++ elements of its kernel to generate a proper submodule.
++ If successful a list which contains first the list of the
++ representations of the submodule, then a list of the
++ representations of the factor module is returned.
++ Otherwise, if we know that all the kernel is already
++ scanned, Norton's irreducibility test can be used either
++ to prove irreducibility or to find the splitting.
++ Notes: the first 6 tries use Parker's fingerprints.
++ Also, 7 covers the case of three-dimensional kernels over
++ the field with 2 elements.
meatAxe: (L M R, B) -> L L M R
++ meatAxe(aG, randomElements) calls meatAxe(aG,false,6,7),
++ only using Parker's fingerprints, if randomElemnts is false.
++ If it is true, it calls meatAxe(aG,true,25,7),
++ only using random elements.
++ Note that the choice of 25 was rather arbitrary.
++ Also, 7 covers the case of three-dimensional kernels over the field
++ with 2 elements.
meatAxe : (L M R, PI) -> L L M R
++ meatAxe(aG, numberOfTries) calls
++ meatAxe(aG,true,numberOfTries,7).
++ Notes: 7 covers the case of three-dimensional
++ kernels over the field with 2 elements.
scanOneDimSubspaces: (L V R, I) -> V R
++ scanOneDimSubspaces(basis,n) gives a canonical representative
++ of the n-th one-dimensional subspace of the vector space
++ generated by the elements of basis, all from R**n.
++ The coefficients of the representative are of shape
++ (0,...,0,1,...,*), * in R. If the size of R
++ is q, then there are (q**n-1)/(q-1) of them.
++ We first reduce n modulo this number, then find the
++ largest i such that +/[q**i for i in 0..i-1] <= n.
++ Subtracting this sum of powers from n results in an

```

```

    ++ i-digit number to basis q. This fills the positions of the
    ++ stars.

## ResolveLatticeCompletion (RESLATC)

### Exports:

coerce

— package RESLATC ResolveLatticeCompletion —

```

)abbrev package RESLATC ResolveLatticeCompletion
++ Author: Stephen M. Watt
++ Date Created: 1986
++ Date Last Updated: May 30, 1991
++ Description:
++ This package provides coercions for the special types \spadtype{Exit}
++ and \spadtype{Void}.

ResolveLatticeCompletion(S: Type): with
  coerce: S -> Void
    ++ coerce(s) throws all information about s away.
    ++ This coercion allows values of any type to appear
    ++ in contexts where they will not be used.
    ++ For example, it allows the resolution of different types in
    ++ the \spad{then} and \spad{else} branches when an \spad{if}
    ++ is in a context where the resulting value is not used.
  coerce: Exit -> S
    ++ coerce(e) is never really evaluated. This coercion is
    ++ used for formal type correctness when a function will not
    ++ return directly to its caller.

== add
  coerce(s: S): Void == void()
  coerce(e: Exit): S ==
    error "Bug: Should not be able to obtain value of type Exit"

=====
RootsFindingPackage examples
=====

```

This package finds all the roots of a polynomial. If the constant field is not large enough then it returns the list of found zeros and the degree of the extension need to find the other roots missing. If the return degree is 1 then all the roots have been found. If 0 is return for the extension degree then there are an infinite number of zeros, that is you ask for the zeroes of 0. In the case of infinite field a list of all found zeros is kept and for each other call of a function that finds zeroes, a check is made on that list; this is to keep a kind of "canonical" representation of the elements.

SortedCache examples
=====
```

A sorted cache of a cachable set  $S$  is a dynamic structure that keeps the elements of  $S$  sorted and assigns an integer to each element of  $S$  once it is in the cache. This way, equality and ordering on  $S$  are tested directly on the integers associated with the elements of  $S$ , once they have been entered in the cache.

=====

SquareFreeRegularSetDecompositionPackage examples

=====

A package providing a new algorithm for solving polynomial systems by means of regular chains. Two ways of solving are provided: in the sense of Zariski closure (like in Kalkbrener's algorithm) or in the sense of the regular zeros (like in Wu, Wang or Lazard-Moreno methods). This algorithm is valid for any type of regular set. It does not care about the way a polynomial is added in an regular set, or how two quasi-components are compared

(by an inclusion-test), or how the invertibility test is made in the tower of simple extensions associated with a regular set.

These operations are realized respectively by the domain TS and the packages QCMPPK(R,E,V,P,TS) and RSETGCD(R,E,V,P,TS).

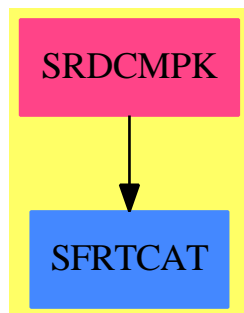

The same way it does not care about the way univariate polynomial gcds (with coefficients in the tower of simple extensions associated with a regular set) are computed. The only requirement is that these gcds need to have invertible initials (normalized or not).

WARNING. There is no need for a user to call directly any operation of this package since they can be accessed by the domain \axiomType{TS}. Thus, the operations of this package are not documented.

=====

SquareFreeRegularTriangularSetGcdPackage examples

=====

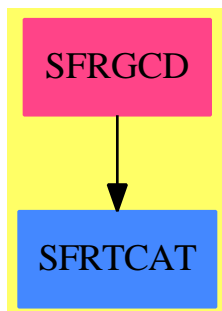

A internal package for computing gcds and resultants of univariate polynomials with coefficients in a tower of simple extensions of a field. There is no need to use directly this package since its main operations are available from TS.

++ Author: Clifton J. Williamson
++ Date Created: 18 July 1990
++ Date Last Updated: 18 July 1990
++ Description:
++ This package provides standard arithmetic operations on matrices.
++ The functions in this package store the results of computations
++ in existing matrices, rather than creating new matrices. This
++ package works only for matrices of type Matrix and uses the
++ internal representation of this type.

StorageEfficientMatrixOperations(R): Exports == Implementation where
  R      : Ring
  M      ==> Matrix R
  NNI    ==> NonNegativeInteger
  ARR    ==> PrimitiveArray R
  REP    ==> PrimitiveArray PrimitiveArray R

Exports ==> with
  copy_! : (M,M) -> M
    ++ \spad{copy!(c,a)} copies the matrix \spad{a} into the matrix c.
    ++ Error: if \spad{a} and c do not have the same
    ++ dimensions.
  plus_! : (M,M,M) -> M
    ++ \spad{plus!(c,a,b)} computes the matrix sum \spad{a + b} and stores the
    ++ result in the matrix c.
    ++ Error: if \spad{a}, b, and c do not have the same dimensions.
  minus_! : (M,M) -> M
    ++ \spad{minus!(c,a)} computes \spad{-a} and stores the result in the

```

```

++ matrix c.
++ Error: if a and c do not have the same dimensions.
minus_! : (M,M,M) -> M
++ \spad{!minus!(c,a,b)} computes the matrix difference \spad{a - b}
++ and stores the result in the matrix c.
++ Error: if \spad{a}, b, and c do not have the same dimensions.
leftScalarTimes_! : (M,R,M) -> M
++ \spad{leftScalarTimes!(c,r,a)} computes the scalar product
++ \spad{r * a} and stores the result in the matrix c.
++ Error: if \spad{a} and c do not have the same dimensions.
rightScalarTimes_! : (M,M,R) -> M
++ \spad{rightScalarTimes!(c,a,r)} computes the scalar product
++ \spad{a * r} and stores the result in the matrix c.
++ Error: if \spad{a} and c do not have the same dimensions.
times_! : (M,M,M) -> M
++ \spad{times!(c,a,b)} computes the matrix product \spad{a * b}
++ and stores the result in the matrix c.
++ Error: if \spad{a}, b, and c do not have
++ compatible dimensions.
power_! : (M,M,M,M,NNI) -> M
++ \spad{power!(a,b,c,m,n)} computes m ** n and stores the result in
++ \spad{a}. The matrices b and c are used to store intermediate results.
++ Error: if \spad{a}, b, c, and m are not square
++ and of the same dimensions.
"***" : (M,NNI) -> M
++ \spad{x ** n} computes the n-th power
++ of a square matrix. The power n is assumed greater than 1.

=====
StreamTaylorSeriesOperations examples
=====
```

StreamTaylorSeriesOperations implements Taylor series arithmetic,  
where a Taylor series is represented by a stream of its coefficients.

Problems raising a UTS to a negative integer power.

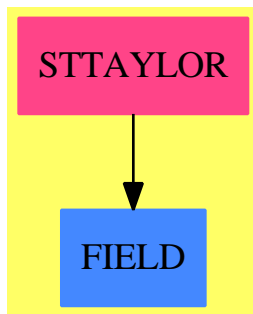

The code in `powern(rn,x)` which raises an unnecessary error  
where no distinction between rational and integer powers are made.

The fix is easy. Since the problem does not exist in SUPS we can  
just take the definition there.

Exports ==> with
"+"      : (ST A,ST A) -> ST A
++ a + b returns the power series sum of \spad{a} and \spad{b}:
++ \spad{[a0,a1,...] + [b0,b1,...] = [a0 + b0,a1 + b1,...]}
"-"      : (ST A,ST A) -> ST A
++ a - b returns the power series difference of \spad{a} and
++ \spad{b}: \spad{[a0,a1,...] - [b0,b1,...] = [a0 - b0,a1 - b1,...]}
"_"      : ST A -> ST A
++ - a returns the power series negative of \spad{a}:
++ \spad{- [a0,a1,...] = [- a0,- a1,...]}
"*"      : (ST A,ST A) -> ST A
++ a * b returns the power series (Cauchy) product of \spad{a} and b:
++ \spad{[a0,a1,...] * [b0,b1,...] = [c0,c1,...]} where
++ \spad{ck = sum(i + j = k, ai * bk)}.
"*"      : (A,ST A) -> ST A
++ r * a returns the power series scalar multiplication of r by \spad{a}:
++ \spad{r * [a0,a1,...] = [r * a0,r * a1,...]}
"*"      : (ST A,A) -> ST A
++ a * r returns the power series scalar multiplication of \spad{a} by r:
++ \spad{[a0,a1,...] * r = [a0 * r,a1 * r,...]}
"exquo"   : (ST A,ST A) -> Union(ST A,"failed")
++ exquo(a,b) returns the power series quotient of \spad{a} by b,
++ if the quotient exists, and "failed" otherwise
"/"       : (ST A,ST A) -> ST A
++ a / b returns the power series quotient of \spad{a} by b.
++ An error message is returned if \spad{b} is not invertible.
++ This function is used in fixed point computations.
recip     : ST A -> UN
++ recip(a) returns the power series reciprocal of \spad{a}, or
++ "failed" if not possible.
monom     : (A,I) -> ST A
++ monom(deg,coef) is a monomial of degree deg with coefficient
++ coef.
integers  : I -> ST I
++ integers(n) returns \spad{[n,n+1,n+2,...]}.
oddintegers : I -> ST I
++ oddintegers(n) returns \spad{[n,n+2,n+4,...]}.
int       : A -> ST A
++ int(r) returns [r,r+1,r+2,...], where r is a ring element.
mapmult   : (ST A,ST A) -> ST A
++ mapmult([a0,a1,...],[b0,b1,...])
++ returns \spad{[a0*b0,a1*b1,...]}.
deriv     : ST A -> ST A
++ deriv(a) returns the derivative of the power series with
++ respect to the power series variable. Thus
++ \spad{deriv([a0,a1,a2,...])} returns \spad{[a1,2 a2,3 a3,...]}.
gderiv    : (I -> A,ST A) -> ST A
++ gderiv(f,[a0,a1,a2,...]) returns
++ \spad{[f(0)*a0,f(1)*a1,f(2)*a2,...]}.

```

```

coerce      : A -> ST A
++ coerce(r) converts a ring element r to a stream with one element.
eval        : (ST A,A) -> ST A
++ eval(a,r) returns a stream of partial sums of the power series
++ \spad{a} evaluated at the power series variable equal to r.
compose     : (ST A,ST A) -> ST A
++ compose(a,b) composes the power series \spad{a} with
++ the power series b.
lagrange    : ST A -> ST A
++ lagrange(g) produces the power series for f where f is
++ implicitly defined as \spad{f(z) = z*g(f(z))}.
revert      : ST A -> ST A
++ revert(a) computes the inverse of a power series \spad{a}
++ with respect to composition.
++ the series should have constant coefficient 0 and first
++ order coefficient 1.
adddiag     : ST ST A -> ST A
++ adddiag(x) performs diagonal addition of a stream of streams. if x =
++ \spad{[[a<0,0>,a<0,1>,...],[a<1,0>,a<1,1>,...],[a<2,0>,a<2,1>,...],...]}
++ and \spad{adddiag(x) = [b<0,b<1>,...], then b<k> = sum(i+j=k,a<i,j>)}.
lambert     : ST A -> ST A
++ lambert(st) computes \spad{f(x) + f(x**2) + f(x**3) + ...}
++ if st is a stream representing \spad{f(x)}.
++ This function is used for computing infinite products.
++ If \spad{f(x)} is a power series with constant coefficient 1 then
++ \spad{prod(f(x**n),n = 1..infinity) = exp(lambert(log(f(x))))}.
oddlambert  : ST A -> ST A
++ oddlambert(st) computes \spad{f(x) + f(x**3) + f(x**5) + ...}
++ if st is a stream representing \spad{f(x)}.
++ This function is used for computing infinite products.
++ If f(x) is a power series with constant coefficient 1 then
++ \spad{prod(f(x**(2*n-1)),n=1..infinity) = exp(oddlambert(log(f(x))))}.
evenlambert : ST A -> ST A
++ evenlambert(st) computes \spad{f(x**2) + f(x**4) + f(x**6) + ...}
++ if st is a stream representing \spad{f(x)}.
++ This function is used for computing infinite products.
++ If \spad{f(x)} is a power series with constant coefficient 1, then
++ \spad{prod(f(x**(2*n)),n=1..infinity) = exp(evenlambert(log(f(x))))}.
generalLambert : (ST A,I,I) -> ST A
++ generalLambert(f(x),a,d) returns
++ \spad{f(x**a) + f(x**(a + d)) + f(x**(a + 2 d)) + ...}.
++ \spad{f(x)} should have zero constant
++ coefficient and \spad{a} and d should be positive.
multisect   : (I,I,ST A) -> ST A
++ multisect(a,b,st)
++ selects the coefficients of \spad{x**((a+b)*n+a)},
++ and changes them to \spad{x**n}.
invmultisect : (I,I,ST A) -> ST A
++ invmultisect(a,b,st) substitutes \spad{x**((a+b)*n)} for \spad{x**n}
++ and multiplies by \spad{x**b}.

```

```

if A has Algebra RN then
  integrate : (A,ST A) -> ST A
    ++ integrate(r,a) returns the integral of the power series \spad{a}
    ++ with respect to the power series variableintegration where
    ++ r denotes the constant of integration. Thus
    ++ \spad{integrate(a,[a0,a1,a2,...]) = [a,a0,a1/2,a2/3,...]}.
  lazyIntegrate : (A,() -> ST A) -> ST A
    ++ lazyIntegrate(r,f) is a local function
    ++ used for fixed point computations.
  nlde      : ST ST A -> ST A
    ++ nlde(u) solves a
    ++ first order non-linear differential equation described by u of the
    ++ form \spad{[[b<0,0>,b<0,1>,...],[b<1,0>,b<1,1>,...]}.
    ++ the differential equation has the form
    ++ \spad{y'=sum(i=0 to infinity,j=0 to infinity,b<i,j>*(x**i)*(y**j))}.
  powern : (RN,ST A) -> ST A
    ++ powern(r,f) raises power series f to the power r.
if A has Field then
  mapdiv      : (ST A,ST A) -> ST A
    ++ mapdiv([a0,a1,...],[b0,b1,...]) returns
    ++ \spad{[a0/b0,a1/b1,...]}.
  lazyGintegrate : (I -> A,A,() -> ST A) -> ST A
    ++ lazyGintegrate(f,r,g) is used for fixed point computations.
  power      : (A,ST A) -> ST A
    ++ power(a,f) returns the power series f raised to the power \spad{a}.

++ Date Last Updated: 14 April 1992
++ Description:
++ StructuralConstantsPackage provides functions creating
++ structural constants from a multiplication tables or a basis
++ of a matrix algebra and other useful functions in this context.

StructuralConstantsPackage(R:Field): public == private where

  L ==> List
  S ==> Symbol
  FRAC ==> Fraction
  POLY ==> Polynomial
  V ==> Vector
  M ==> Matrix
  REC ==> Record(particular: Union(V R,"failed"),basis: List V R)
  LSMP ==> LinearSystemMatrixPackage(R,V R,V R, M R)

public ==> with
  -- what we really want to have here is a matrix over

```

```

-- linear polynomials in the list of symbols, having arbitrary
-- coefficients from a ring extension of R, e.g. FRAC POLY R.
structuralConstants : (L S, M FRAC POLY R) -> V M FRAC POLY R
  ++ structuralConstants(ls,mt) determines the structural constants
  ++ of an algebra with generators ls and multiplication table mt, the
  ++ entries of which must be given as linear polynomials in the
  ++ indeterminates given by ls. The result is in particular useful
  ++ as fourth argument for \spadtype{AlgebraGivenByStructuralConstants}
  ++ and \spadtype{GenericNonAssociativeAlgebra}.
structuralConstants : (L S, M POLY R) -> V M POLY R
  ++ structuralConstants(ls,mt) determines the structural constants
  ++ of an algebra with generators ls and multiplication table mt, the
  ++ entries of which must be given as linear polynomials in the
  ++ indeterminates given by ls. The result is in particular useful
  ++ as fourth argument for \spadtype{AlgebraGivenByStructuralConstants}
  ++ and \spadtype{GenericNonAssociativeAlgebra}.
structuralConstants: L M R -> V M R
  ++ structuralConstants(basis) takes the basis of a matrix
  ++ algebra, e.g. the result of \spadfun{basisOfCentroid} and calculates
  ++ the structural constants.
  ++ Note, that the it is not checked, whether basis really is a
  ++ basis of a matrix algebra.
coordinates: (M R, L M R) -> V R
  ++ coordinates(a,[v1,...,vn]) returns the coordinates of \spad{a}
  ++ with respect to the \spad{R}-module basis \spad{v1},...,\spad{vn}.

Symbolic solver for systems of rational functions with coefficients in an integral domain  $R$ .

The systems are solved in the field of rational functions over  $R$ . Solutions are exact of the form  $\text{variable} = \text{value}$  when the value is a member of the coefficient domain  $R$ . Otherwise the solutions are implicitly expressed as roots of univariate polynomial equations over  $R$ .

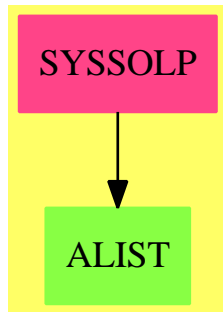

Care is taken to guarantee that the denominators of the input equations do not vanish on the solution sets.

The arguments to solve can either be given as equations or as rational functions interpreted as equal to zero. The user can specify an explicit list of symbols to be solved for, treating all other symbols appearing as parameters or omit the list of symbols in which case the system tries to solve with respect to all symbols appearing in the input.

-- IS THERE A WORKING DOMAIN Tableau ??
-- coerce : M I -> Tableau(I)
-- ++ coerce(ytab) coerces the Young-Tableau ytab to an element of
-- ++ the domain Tableau(I).

coleman : (L I, L I, L I) -> M I
++ coleman(alpha,beta,pi):
++ there is a bijection from the set of matrices having nonnegative
++ entries and row sums alpha, column sums beta
++ to the set of  $Salpha - Sbeta$  double cosets of the
++ symmetric group  $S_n$ . ( $Salpha$  is the Young subgroup
++ corresponding to the improper partition alpha).
++ For a representing element pi of such a double coset,
++ coleman(alpha,beta,pi) generates the Coleman-matrix
++ corresponding to alpha, beta, pi.
++ Note that The permutation pi of  $\{1,2,\dots,n\}$  has to be given
++ in list form.
++ Note that the inverse of this map is inverseColeman
++ (if pi is the lexicographical smallest permutation
++ in the coset). For details see James/Kerber.
inverseColeman : (L I, L I, M I) -> L I
++ inverseColeman(alpha,beta,C):
++ there is a bijection from the set of matrices having nonnegative
++ entries and row sums alpha, column sums beta
++ to the set of  $Salpha - Sbeta$  double cosets of the
++ symmetric group  $S_n$ . ( $Salpha$  is the Young subgroup
++ corresponding to the improper partition alpha).
++ For such a matrix C, inverseColeman(alpha,beta,C)

```

```

++ calculates the lexicographical smallest pi in the
++ corresponding double coset.
++ Note that the resulting permutation pi of {1,2,...,n}
++ is given in list form.
++ Notes: the inverse of this map is coleman.
++ For details, see James/Kerber.
listYoungTableaus : (L I) -> L M I
++ listYoungTableaus(lambda) where lambda is a proper partition
++ generates the list of all standard tableaux of shape lambda
++ by means of lattice permutations. The numbers of the lattice
++ permutation are interpreted as column labels. Hence the
++ contents of these lattice permutations are the conjugate of
++ lambda.
++ Notes: the functions nextLatticePermutation and
++ makeYoungTableau are used.
++ The entries are from 0,...,n-1.
makeYoungTableau : (L I, L I) -> M I
++ makeYoungTableau(lambda,gitter) computes for a given lattice
++ permutation gitter and for an improper partition lambda
++ the corresponding standard tableau of shape lambda.
++ Notes: see listYoungTableaus.
++ The entries are from 0,...,n-1.
nextColeman : (L I, L I, M I) -> M I
++ nextColeman(alpha,beta,C) generates the next Coleman matrix
++ of column sums alpha and row sums beta according
++ to the lexicographical order from bottom-to-top.
++ The first Coleman matrix is achieved by C=new(1,1,0).
++ Also, new(1,1,0) indicates that C is the last Coleman matrix.
nextLatticePermutation : (L I, L I, B) -> L I
++ nextLatticePermutation(lambda,lattP,constructNotFirst) generates
++ the lattice permutation according to the proper partition
++ lambda succeeding the lattice permutation lattP in
++ lexicographical order as long as constructNotFirst is true.
++ If constructNotFirst is false, the first lattice permutation
++ is returned.
++ The result nil indicates that lattP has no successor.
nextPartition : (V I, V I, I) -> V I
++ nextPartition(gamma,part,number) generates the partition of
++ number which follows part according to the right-to-left
++ lexicographical order. The partition has the property that
++ its components do not exceed the corresponding components of
++ gamma. The first partition is achieved by part=[].
++ Also, [] indicates that part is the last partition.
nextPartition : (L I, V I, I) -> V I
++ nextPartition(gamma,part,number) generates the partition of
++ number which follows part according to the right-to-left
++ lexicographical order. The partition has the property that
++ its components do not exceed the corresponding components of
++ gamma. the first partition is achieved by part=[].
++ Also, [] indicates that part is the last partition.

```

```

numberOfImproperPartitions: (I,I) -> I
  ++ numberOfImproperPartitions(n,m) computes the number of partitions
  ++ of the nonnegative integer n in m nonnegative parts with regarding
  ++ the order (improper partitions).
  ++ Example: numberOfImproperPartitions (3,3) is 10,
  ++ since [0,0,3], [0,1,2], [0,2,1], [0,3,0], [1,0,2], [1,1,1],
  ++ [1,2,0], [2,0,1], [2,1,0], [3,0,0] are the possibilities.
  ++ Note that this operation has a recursive implementation.
subSet : (I,I,I) -> L I
  ++ subSet(n,m,k) calculates the k-th m-subset of the set
  ++ 0,1,...,(n-1) in the lexicographic order considered as
  ++ a decreasing map from 0,...,(m-1) into 0,...,(n-1).
  ++ See S.G. Williamson: Theorem 1.60.
  ++ Error: if not (0 <= m <= n and 0 <= k < (n choose m)).
unrankImproperPartitions0 : (I,I,I) -> L I
  ++ unrankImproperPartitions0(n,m,k) computes the k-th improper
  ++ partition of nonnegative n in m nonnegative parts in reverse
  ++ lexicographical order.
  ++ Example: [0,0,3] < [0,1,2] < [0,2,1] < [0,3,0] <
  ++ [1,0,2] < [1,1,1] < [1,2,0] < [2,0,1] < [2,1,0] < [3,0,0].
  ++ Error: if k is negative or too big.
  ++ Note that counting of subtrees is done by
  ++ numberOfImproperPartitions
unrankImproperPartitions1: (I,I,I) -> L I
  ++ unrankImproperPartitions1(n,m,k) computes the k-th improper
  ++ partition of nonnegative n in at most m nonnegative parts
  ++ ordered as follows: first, in reverse
  ++ lexicographically according to their non-zero parts, then
  ++ according to their positions (i.e. lexicographical order
  ++ using subSet: [3,0,0] < [0,3,0] < [0,0,3] < [2,1,0] <
  ++ [2,0,1] < [0,2,1] < [1,2,0] < [1,0,2] < [0,1,2] < [1,1,1].
  ++ Note that counting of subtrees is done by
  ++ numberOfImproperPartitionsInternal.

TabulatedComputationPackage(Key ,Entry) provides some modest support for dealing with operations with type Key -> Entry. The result of such operations can be stored and retrieved with this package by using a hash-table. The user does not need to worry about the management of this hash-table. However, onnly one hash-table is built by calling TabulatedComputationPackage(Key ,Entry).

=====

TaylorSolve examples

=====

UTSSOL is a facility to compute the first few coefficients of a Taylor series given only implicitly by a function *f* that vanishes when applied to the Taylor series.

It uses the method of undetermined coefficients.

Could I either

take a function `UTSCAT F $->$ UTSCAT F` and still be able to compute with undetermined coefficients, or  
take a function `F $->$ F`, and do likewise?

Let's see.

Try to compute the equation without resorting to power series. I.e., %  
`c: SUP SUP F`, and `f: SUP SUP F $->$ SUP SUP F`. Won't this make the computation of coefficients terribly slow?

I could also try to replace transcendental kernels with variables\dots

Unfortunately, `SUP F` does not have `TRANFUN` -- well, it can't, of course. However, I'd like to be able to compute %  
`sin(1+monomial(1,1)$UFPS SUP EXPR INT)`.

## TaylorSolve (UTSSOL)

**Exports:**  
seriesSolve

— package UTSSOL TaylorSolve —

```

)abbrev package UTSSOL TaylorSolve
++ Description:
++ This package has no description

TaylorSolve(F, UTSF, UTSSUPF): Exports == Implementation where
  F: Field
  SUP ==> SparseUnivariatePolynomialExpressions
  UTSF: UnivariateTaylorSeriesCategory F
  UTSSUPF: UnivariateTaylorSeriesCategory SUP F
  NNI ==> NonNegativeInteger

  Exports == with
    seriesSolve: (UTSSUPF -> UTSSUPF, List F) -> UTSF

  Implementation == add
\getchunk{implementation: UTSSOL TaylorSolve}

```

— implementation: UTSSOL TaylorSolve —

```

seriesSolve(f, l) ==
  c1 :=
    map((x:F):SUP F +-> x::(SUP F), l)
    $ListFunctions2(F, SUP F)::(Stream SUP F)
  coeffs: Stream SUP F := concat(c1, generate(monomial(1$F,1$NNI)))
--
  coeffs: Stream SUP F := concat(c1, monomial(1$F,1$NNI))

```

coeffs is the stream of the already computed coefficients of the solution, plus one which is so far undetermined. We store in st.2 the complete stream and in st.1 the stream starting with the first coefficient that has possibly not yet been computed.

The mathematics is not quite worked out. If coeffs is initialized as stream with all coefficients set to the *same* transcendental value, and not enough initial values are given, then the missing ones are implicitly assumed to be all identical. It may well happen that a solution is produced, although it is not uniquely determined\dots

— implementation: UTSSOL TaylorSolve —

```
st: List Stream SUP F := [coeffs, coeffs]
```

Consider an arbitrary equation  $f(x, y(x)) = 0$ . When setting  $x = 0$ , we obtain  $f(0, y(0)) = 0$ . It is not necessarily the case that this determines  $y(0)$  uniquely, so we need one initial value that satisfies this equation.

seriesSolve should check that the given initial values satisfy  $f(0, y(0), y'(0), \dots) = 0$ .

Now consider the derivatives of  $f$ , where we write  $y$  instead of  $y(x)$  for better readability:

$$\frac{d}{dx}f(x, y) = f_1(x, y) + f_2(x, y)y'$$

and

$$\begin{aligned} \frac{d^2}{dx^2}f(x, y) &= f_{1,1}(x, y) \\ &\quad + f_{1,2}(x, y)y'^{\prime} \\ &\quad + f_{2,1}(x, y)y'^{\prime} \\ &\quad + f_{2,2}(x, y)(y'^{\prime})^2 \\ &\quad + f_{2,2}(x, y)y'^{\prime\prime}. \end{aligned}$$

In general,  $\frac{d^2}{dx^2}f(x, y)$  depends only linearly on  $y''$ .

This points to another possibility: Since we know that we only need to solve linear equations, we could compute two values and then use interpolation. This might be a bit slower, but more importantly: can we still check that we have enough initial values? Furthermore, we then really need that  $f$  is analytic, i.e., operators are not necessarily allowed anymore. However, it seems that composition is allowed.

— implementation: UTSSOL TaylorSolve —

```

next: () -> F :=
  nr := st.1
  res: F

  if ground?(coeff: SUP F := nr.1)$(SUP F)

```

---

If the next element was already calculated, we can simply return it:

— implementation: UTSSOL TaylorSolve —

```

then
  res := ground coeff
  st.1 := rest nr
else

```

---

Otherwise, we have to find the first non-satisfied relation and solve it. It should be linear, or a single non-constant monomial. That is, the solution should be unique.

— implementation: UTSSOL TaylorSolve —

```

ns := st.2
eqs: Stream SUP F := coefficients f series ns
while zero? first eqs repeat eqs := rest eqs
eq: SUP F := first eqs
if degree eq > 1 then
  if monomial? eq then res := 0
else
  output(hconcat("The equation is: ", eq::OutputForm))
  $OutputPackage
  error "seriesSolve: equation for coefficient not linear"
else res := (-coefficient(eq, 0$NNI)$(SUP F)
  /coefficient(eq, 1$NNI)$(SUP F))

nr.1 := res::SUP F
-- concat!(st.2, monomial(1$F,1$NNI))
st.1 := rest nr

res

```

Implementation ==> add

---

I have had to work my way around the following bug in the compiler: When a local variable is given a mapping as a value, e.g.

```
foo : SF -> SF := makeFloatFunction(f,t),
```

the compiler cannot distinguish that local variable from a local function defined elsewhere in the package. Thus, when 'foo' is passed to a function, e.g.

```
bird := fcn(foo),
```

foo will often be compiled as DRAW;foo rather than foo. This, of course, causes a run-time error.

To avoid this problem, local variables are not given mappings as values, but rather (singleton) lists of mappings. The first element of the list can always be extracted and everything goes through as before. There is no major loss in efficiency, as the computation of points will always dominate the computation time.

---

The function `myTrap1` is a local function for used in creating maps SF -> Point SF (two dimensional). The range of this function is SingleFloat. As originally coded it would return `$NaNvalue$Lisp` which is outside the range. Since this function is only used internally by the draw package we handle the “failed” case by returning zero. We handle the out-of-range

case by returning the maximum or minimum SingleFloat value.

## TopLevelDrawFunctionsForPoints (DRAWPT)

**Exports:**

draw

— package DRAWPT TopLevelDrawFunctionsForPoints —

```
)abbrev package DRAWPT TopLevelDrawFunctionsForPoints
++ Author: Mike Dewar
++ Date Created: 24 May 1995
```

```

++ Date Last Updated: 25 November 1996
++ Description:
++ TopLevelDrawFunctionsForPoints provides top level functions
++ for drawing curves and surfaces described by sets of points.

TopLevelDrawFunctionsForPoints(): Exports == Implementation where

DROP ==> DrawOption
L ==> List
SF ==> DoubleFloat
Pt ==> Point SF
VIEW2 ==> TwoDimensionalViewport
VIEW3 ==> ThreeDimensionalViewport

Exports ==> with
  draw: (L SF, L SF) -> VIEW2
    ++ draw(lx,ly) plots the curve constructed of points (x,y) for x
    ++ in \spad{lx} for y in \spad{ly}.
  draw: (L SF, L SF, L DROP) -> VIEW2
    ++ draw(lx,ly,l) plots the curve constructed of points (x,y) for x
    ++ in \spad{lx} for y in \spad{ly}.
    ++ The options contained in the list l of
    ++ the domain \spad{DrawOption} are applied.
  draw: (L Pt) -> VIEW2
    ++ draw(lp) plots the curve constructed from the list of points lp.
  draw: (L Pt, L DROP) -> VIEW2
    ++ draw(lp,l) plots the curve constructed from the list of points lp.
    ++ The options contained in the list l of the domain \spad{DrawOption}
    ++ are applied.
  draw: (L SF, L SF, L SF) -> VIEW3
    ++ draw(lx,ly,lz) draws the surface constructed by projecting the values
    ++ in the \axiom{lz} list onto the rectangular grid formed by the
    ++ \axiom{lx x ly}.
  draw: (L SF, L SF, L SF, L DROP) -> VIEW3
    ++ draw(lx,ly,lz,l) draws the surface constructed by
    ++ projecting the values
    ++ in the \axiom{lz} list onto the rectangular grid formed by the
    ++ The options contained in the list l of the domain \spad{DrawOption}
    ++ are applied.

Implementation ==> add

PRODUCT ==> Record(coef : Z, var : K)
FPR    ==> Fraction Polynomial R

Exports ==> with
  expand      : F -> F
    ++ expand(f) performs the following expansions on f:\begin{items}
    ++ \item 1. logs of products are expanded into sums of logs,
    ++ \item 2. trigonometric and hyperbolic trigonometric functions
    ++ of sums are expanded into sums of products of trigonometric
    ++ and hyperbolic trigonometric functions.
    ++ \item 3. formal powers of the form \spad{(a/b)**c} are expanded into
    ++ \spad{a**c * b**(-c)}.
    ++ \end{items}
  simplify   : F -> F
    ++ simplify(f) performs the following simplifications on f:\begin{items}
    ++ \item 1. rewrites trigs and hyperbolic trigs in terms
    ++ of \spad{sin}, \spad{cos}, \spad{sinh}, \spad{cosh}.
    ++ \item 2. rewrites \spad{sin**2} and \spad{sinh**2} in terms

```

```

++ of \spad{cos} and \spad{cosh},
++ \item 3. rewrites \spad{exp(a)*exp(b)} as \spad{exp(a+b)}.
++ \item 4. rewrites \spad{(a**(1/n))**m * (a**(1/s))**t} as a single
++ power of a single radical of \spad{a}.
++ \end{items}
htrigs      : F -> F
++ htrigs(f) converts all the exponentials in f into
++ hyperbolic sines and cosines.
simplifyExp: F -> F
++ simplifyExp(f) converts every product \spad{exp(a)*exp(b)}
++ appearing in f into \spad{exp(a+b)}.
simplifyLog : F -> F
++ simplifyLog(f) converts every \spad{log(a) - log(b)} appearing in f
++ into \spad{log(a/b)}, every \spad{log(a) + log(b)} into \spad{log(a*b)}
++ and every \spad{n*log(a)} into \spad{log(a^n)}.
expandPower: F -> F
++ expandPower(f) converts every power \spad{(a/b)**c} appearing
++ in f into \spad{a**c * b**(-c)}.
expandLog   : F -> F
++ expandLog(f) converts every \spad{log(a/b)} appearing in f into
++ \spad{log(a) - log(b)}, and every \spad{log(a*b)} into
++ \spad{log(a) + log(b)}..
cos2sec     : F -> F
++ cos2sec(f) converts every \spad{cos(u)} appearing in f into
++ \spad{1/sec(u)}.
cosh2sech   : F -> F
++ cosh2sech(f) converts every \spad{cosh(u)} appearing in f into
++ \spad{1/sech(u)}.
cot2trig    : F -> F
++ cot2trig(f) converts every \spad{cot(u)} appearing in f into
++ \spad{cos(u)/sin(u)}.
coth2trigh  : F -> F
++ coth2trigh(f) converts every \spad{coth(u)} appearing in f into
++ \spad{cosh(u)/sinh(u)}.
csc2sin     : F -> F
++ csc2sin(f) converts every \spad{csc(u)} appearing in f into
++ \spad{1/sin(u)}.
csch2sinh   : F -> F
++ csch2sinh(f) converts every \spad{csch(u)} appearing in f into
++ \spad{1/sinh(u)}.
sec2cos     : F -> F
++ sec2cos(f) converts every \spad{sec(u)} appearing in f into
++ \spad{1/cos(u)}.
sech2cosh   : F -> F
++ sech2cosh(f) converts every \spad{sech(u)} appearing in f into
++ \spad{1/cosh(u)}.
sin2csc     : F -> F
++ sin2csc(f) converts every \spad{sin(u)} appearing in f into
++ \spad{1/csc(u)}.
sinh2csch   : F -> F

```

```

    ++ sinh2csch(f) converts every \spad{sinh(u)} appearing in f into
    ++ \spad{1/csch(u)}.
tan2trig : F -> F
    ++ tan2trig(f) converts every \spad{tan(u)} appearing in f into
    ++ \spad{sin(u)/cos(u)}.
tanh2trigh : F -> F
    ++ tanh2trigh(f) converts every \spad{tanh(u)} appearing in f into
    ++ \spad{sinh(u)/cosh(u)}.
tan2cot : F -> F
    ++ tan2cot(f) converts every \spad{tan(u)} appearing in f into
    ++ \spad{1/cot(u)}.
tanh2coth : F -> F
    ++ tanh2coth(f) converts every \spad{tanh(u)} appearing in f into
    ++ \spad{1/coth(u)}.
cot2tan : F -> F
    ++ cot2tan(f) converts every \spad{cot(u)} appearing in f into
    ++ \spad{1/tan(u)}.
coth2tanh : F -> F
    ++ coth2tanh(f) converts every \spad{coth(u)} appearing in f into
    ++ \spad{1/tanh(u)}.
removeCosSq: F -> F
    ++ removeCosSq(f) converts every \spad{cos(u)**2} appearing in f into
    ++ \spad{1 - sin(x)**2}, and also reduces higher
    ++ powers of \spad{cos(u)} with that formula.
removeSinSq: F -> F
    ++ removeSinSq(f) converts every \spad{sin(u)**2} appearing in f into
    ++ \spad{1 - cos(x)**2}, and also reduces higher powers of
    ++ \spad{sin(u)} with that formula.
removeCoshSq:F -> F
    ++ removeCoshSq(f) converts every \spad{cosh(u)**2} appearing in f into
    ++ \spad{1 - sinh(x)**2}, and also reduces higher powers of
    ++ \spad{cosh(u)} with that formula.
removeSinhSq:F -> F
    ++ removeSinhSq(f) converts every \spad{sinh(u)**2} appearing in f into
    ++ \spad{1 - cosh(x)**2}, and also reduces higher powers
    ++ of \spad{sinh(u)} with that formula.
if R has PatternMatchable(R) and R has ConvertibleTo(Pattern(R))
and F has ConvertibleTo(Pattern(R)) and F has PatternMatchable R then
expandTrigProducts : F -> F
    ++ expandTrigProducts(e) replaces \axiom{sin(x)*sin(y)} by
    ++ \spad{(cos(x-y)-cos(x+y))/2}, \axiom{cos(x)*cos(y)} by
    ++ \spad{(cos(x-y)+cos(x+y))/2}, and \axiom{sin(x)*cos(y)} by
    ++ \spad{(sin(x-y)+sin(x+y))/2}. Note that this operation uses
    ++ the pattern matcher and so is relatively expensive. To avoid
    ++ getting into an infinite loop the transformations are applied
    ++ at most ten times.

```

## The htrigs function

The htrigs function can be used to replace and reduce hyperbolic trigonometric identities.

The identity for  $\sinh(x)$  is  $(\exp(x) - \exp(-x))/2$

If we difference these we should get zero

$$f := \sinh(x) - (\exp(x) - \exp(-x))/2$$

instead, by default, we get

$$\frac{2\sinh(x) - \frac{x}{e} + \frac{-x}{e}}{2}$$

The function htrigs(f) gives 0

This works as follows:

```

m:=mainKernel f => sinh(x)
Type: Union(Kernel(Expression(Integer)),...)

```

which is coerced to the first part of the union:

```
k:=m::Kernel(Expression(Integer))
```

and the operator is extracted:

```
op:=operator(k) ==> sinh
                                     Type: BasicOperator
```

The argument function extracts the variable used as arguments:

```
argument k ==> [x]
                                     Type: Kernel(Expression(Integer))
```

At this point we have picked apart the main Kernel into its operator and its arguments. We now process the list of arguments.

The function htrigs is called on every element of the argument list, which in this case, returns a list:

```
arg:=[htrigs x for x in argument k]$List(Expression(Integer))
==> [x]
                                     Type: List(Expression(Integer))
```

We form a polynomial by replacing the kernel in the numerator with ?

```
num := univariate(numer f, k)

      x      -x
2? - %e  + %e
                                     Type: SparseUnivariatePolynomial(
                                     SparseMultivariatePolynomial(
                                     Integer, Kernel(Expression(Integer))))
```

and a polynomial of the denominator, replacing the kernel

```
den := univariate(denom f, k)

      2
                                     Type: SparseUnivariatePolynomial(
                                     SparseMultivariatePolynomial(
                                     Integer, Kernel(Expression(Integer))))
```

In this case the op is not the exponential so we are doing straight trig substitution. We reconstruct the function call using the op and arg values, that is:

```
g1 := op arg ==> sinh(x)
                                     Type: Expression(Integer)
```

So sup2htrigs, which is a local function, is used to simplify the parts of the fraction. In this case,

```
sup2htrigs(num, g1:= op arg) ==> 0
                                     Type: Expression(Integer)
```

```
sup2htrigs(den, g1) ==> 2
                                     Type: Expression(Integer)
```

Thus, the result is 0

The identity for  $\cosh(x)$  is  $(\exp(x) + \exp(-x))/2$

If we difference these we should get zero

```
f := cosh(x) - (%e^x + %e^-x)/2
```

instead, by default, we get

$$\frac{-e^x + e^{-x} + 2\cosh(x)}{2}$$

and the function call  $htrigs(f)$  gives 0

This works as follows:

```
m:=mainKernel f => %e^x
                                     Type: Union(Kernel(Expression(Integer)),...)
```

which is coerced to the first part of the union:

```
k:=m::Kernel(Expression(Integer)) => %e^x
                                     Type: Kernel(Expression(Integer))
```

and the operator is extracted:

```
op:=operator(k) => exp
                                     Type: BasicOperator
```

The argument function extracts the variable used as arguments:

```
argument k ==> [x]
                                     Type Kernel(Expression(Integer))
```

At this point we have picked apart the main Kernel into its operator and its arguments. We now process the list of arguments.

The  $htrigs$  function is called on every element of the argument list, which in this case, returns a list:

```
arg:=[htrigs x for x in argument k]$List(Expression(Integer))
=> [x]
```

```
Type: List(Expression(Integer))
```

We form polynomial by replacing the kernel in the numerator with ?

```
num := univariate( numer f, k)
```

```

- x
- ? - %e  + 2cosh(x)
Type: SparseUnivariatePolynomial(
      SparseMultivariatePolynomial(
        Integer, Kernel(Expression(Integer))))
```

and a polynomial of the denominator, replacing the kernel

```
den := univariate( denom f, k)
```

```

2
Type: SparseUnivariatePolynomial(
      SparseMultivariatePolynomial(
        Integer, Kernel(Expression(Integer))))
```

In this case, the expression

```
is?(op, "exp"::Symbol) => true
```

so we form

```
a := first arg => x
Type: Expression(Integer)
```

since we know that

```
cosh(x)+sinh(x) => %ex
```

we can form this use this expression in substitutions

```
g1 := cosh(a)+sinh(a) => sinh(x)+cosh(x)
Type: Expression(Integer)
```

since we know that

```
cosh(x)-sinh(x) => - %e-x
```

we can form this use this expression in substitutions

```
g2 := cosh(a)-sinh(a) => -sinh(x)+cosh(x)
      Type: Expression(Integer)
```

```
b := (degree num)::Integer quo 2 => 0
      Type: NonNegativeInteger
```

The supexp function is using the g1 and g2 identities to replace exp(x)

```
supexp(num,g1,g2,b) => sinh(x)-cosh(x)-sinh(x)+2cosh(x)-cosh(x)
      Type: Expression(Integer)
```

```
supexp(den,g1,g2,b) => 2
      Type: Expression(Integer)
```

which is effectively

```
t1/t2 => (sinh(x)-cosh(x)-sinh(x)+2cosh(x)-cosh(x))/2
      Type: Expression(Integer)
```

the last form of which can be rearranged as:

```
(sinh(x)-sinh(x) + 2cosh(x)-cosh(x)-cosh(x) )/2 => 0
```

so the result is 0

## TranscendentalRischDESystem (RDETRS)

**Exports:**

baseRDEsys monomRDEsys

— package RDETRS TranscendentalRischDESystem —

```

)abbrev package RDETRS TranscendentalRischDESystem
++ Author: Manuel Bronstein
++ Date Created: 17 August 1992
++ Date Last Updated: 3 February 1994
++ Description:
++ Risch differential equation system, transcendental case.

TranscendentalRischDESystem(F, UP): Exports == Implementation where
  F : Join(Field, CharacteristicZero, RetractableTo Integer)
  UP : UnivariatePolynomialCategory F

N ==> NonNegativeInteger
Z ==> Integer
RF ==> Fraction UP
V ==> Vector UP
U ==> Union(List UP, "failed")
REC ==> Record(z1:UP, z2:UP, r1:UP, r2:UP)

Exports ==> with
  monomRDEsys: (RF, RF, RF, UP -> UP) -> _
    Union(Record(a:UP, b:RF, h:UP, c1:RF, c2:RF, t:UP), "failed")
  ++ monomRDEsys(f,g1,g2,D) returns \spad{[A, B, H, C1, C2, T]} such that
  ++ \spad{(y1', y2') + ((0, -f), (f, 0)) (y1,y2) = (g1,g2)} has a solution
  ++ if and only if \spad{y1 = Q1 / T, y2 = Q2 / T},
  ++ where \spad{B,C1,C2,Q1,Q2} have no normal poles and satisfy
  ++ A \spad{(Q1', Q2') + ((H, -B), (B, H)) (Q1,Q2) = (C1,C2)}
  ++ D is the derivation to use.
  baseRDEsys: (RF, RF, RF) -> Union(List RF, "failed")
  ++ baseRDEsys(f, g1, g2) returns fractions \spad{y_1.y_2} such that
  ++ \spad{(y1', y2') + ((0, -f), (f, 0)) (y1,y2) = (g1,g2)}

```

```

++ if \spad{y_1,y_2} exist, "failed" otherwise.

=====

TransSolvePackage examples

=====

This package tries to find solutions of equations of type Expression(R).

This means expressions involving transcendental, exponential, logarithmic and nthRoot functions.

After trying to transform different kernels to one kernel by applying several rules, it calls zerosOf for the SparseUnivariatePolynomial in the remaining kernel.

For example the expression

$\sin(x)\cos(x)-2$

will be transformed to

$-2 \tan(x/2)^4 - 2 \tan(x/2)^3 - 4 \tan(x/2)^2 + 2 \tan(x/2) - 2$

by using the function normalize and then to

$-2 \tan(x)^2 + \tan(x) - 2$

with help of subsTan. This function tries to express the given function in terms of  $\tan(x/2)$  to express in terms of  $\tan(x)$ .

Other examples are the expressions

$\sqrt{x+1} + \sqrt{x+7} + 1$

$\sqrt{\sin(x)} + 1$

$\text{solve}(1/2*v*v*\cos(\theta+\phi)*\cos(\theta+\phi)+g*1*\cos(\phi)=g*1,\phi)$

## TransSolvePackage (SOLVETRA)

### Exports:

solve

— package SOLVETRA TransSolvePackage —

```

)abbrev package SOLVETRA TransSolvePackage
++ Author: W. Wiwianka, Martin Rubey
++ Date Created: Summer 1991
++ Date Last Changed: 9/91
++ Description:
++ This package tries to find solutions of equations of type Expression(R).
++ This means expressions involving transcendental, exponential, logarithmic
++ and nthRoot functions.
++ After trying to transform different kernels to one kernel by applying
++ several rules, it calls zerosOf for the SparseUnivariatePolynomial in
++ the remaining kernel.
++ For example the expression \spad{sin(x)*cos(x)-2} will be transformed to
++ \spad{-2 tan(x/2)**4 -2 tan(x/2)**3 -4 tan(x/2)**2 +2 tan(x/2) -2}
++ by using the function normalize and then to
++ \spad{-2 tan(x)**2 + tan(x) -2}
++ with help of subsTan. This function tries to express the given function
++ in terms of \spad{tan(x/2)} to express in terms of \spad{tan(x)} .
++ Other examples are the expressions \spad{sqrt(x+1)+sqrt(x+7)+1} or
++ \spad{sqrt(sin(x))+1} .

```

This package finds the function func3 where func1 and func2 are given and func1 = func3(func2) . If there is no solution then function func1 will be returned.

An example would be

```
func1:= 8*X**3+32*X**2-14*X ::EXPR INT
```

and

```
func2:=2*X ::EXPR INT
```

convert them via univariate to FRAC SUP EXPR INT and then the solution is

```
func3:=X**3+X**2-X
```

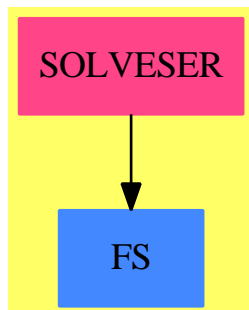

of type FRAC SUP EXPR INT

```

This package provides functions that compute "fraction-free" inverses of upper and lower triangular matrices over a integral domain. By "fraction-free inverses" we mean the following: given a matrix B with entries in R and an element d of R such that  $d * \text{inv}(B)$  also has entries in R, we return  $d * \text{inv}(B)$ . Thus, it is not necessary to pass to the quotient field in any of our computations.

TubePlotTools(): Exports == Implementation where
```

```
  I ==> Integer
  SF ==> DoubleFloat
  L ==> List
  Pt ==> Point SF
```

```
Exports ==> with
```

```
  point: (SF,SF,SF,SF) -> Pt
```

```

++ point(x1,x2,x3,c) creates and returns a point from the three
++ specified coordinates \spad{x1}, \spad{x2}, \spad{x3}, and also
++ a fourth coordinate, c, which is generally used to specify the
++ color of the point.
"*" : (SF,Pt) -> Pt
++ s * p returns a point whose coordinates are the scalar multiple
++ of the point p by the scalar s, preserving the color, or fourth
++ coordinate, of p.
"+" : (Pt,Pt) -> Pt
++ p + q computes and returns a point whose coordinates are the sums
++ of the coordinates of the two points \spad{p} and \spad{q}, using
++ the color, or fourth coordinate, of the first point \spad{p}
++ as the color also of the point \spad{q}.
"-" : (Pt,Pt) -> Pt
++ p - q computes and returns a point whose coordinates are the
++ differences of the coordinates of two points \spad{p} and \spad{q},
++ using the color, or fourth coordinate, of the first point \spad{p}
++ as the color also of the point \spad{q}.
dot : (Pt,Pt) -> SF
++ dot(p,q) computes the dot product of the two points \spad{p}
++ and \spad{q} using only the first three coordinates, and returns
++ the resulting \spadtype{DoubleFloat}.
cross : (Pt,Pt) -> Pt
++ cross(p,q) computes the cross product of the two points \spad{p}
++ and \spad{q} using only the first three coordinates, and keeping
++ the color of the first point p. The result is returned as a point.
unitVector: Pt -> Pt
++ unitVector(p) creates the unit vector of the point p and returns
++ the result as a point. Note that \spad{unitVector(p) = p/|p|}.
cosSinInfo: I -> L L SF
++ cosSinInfo(n) returns the list of lists of values for n, in the form
++ \spad{[[cos(n-1) a,sin(n-1) a],...,[cos 2 a,sin 2 a],[cos a,sin a]]}
++ where \spad{a = 2 pi/n}. Note that n should be greater than 2.
loopPoints: (Pt,Pt,Pt,SF,L L SF) -> L Pt
++ loopPoints(p,n,b,r,lls) creates and returns a list of points
++ which form the loop with radius r, around the center point
++ indicated by the point p, with the principal normal vector of
++ the space curve at point p given by the point(vector) n, and the
++ binormal vector given by the point(vector) b, and a list of lists,
++ lls, which is the \spadfun{cosSinInfo} of the number of points
++ defining the loop.

)abbrev package CLIP TwoDimensionalPlotClipping
++ Author: Clifton J. Williamson
++ Date Created: 22 December 1989
++ Date Last Updated: 10 July 1990
++ Description:
++ Automatic clipping for 2-dimensional plots
++ The purpose of this package is to provide reasonable plots of
++ functions with singularities.

TwoDimensionalPlotClipping(): Exports == Implementation where
  B      ==> Boolean
  L      ==> List
  SEG    ==> Segment
  RN     ==> Fraction Integer
  SF     ==> DoubleFloat
  Pt     ==> Point DoubleFloat
  PLOT   ==> Plot
  CLIPPED ==> Record(brans: L L Pt,xValues: SEG SF,yValues: SEG SF)

Exports ==> with
  clip: PLOT -> CLIPPED
    ++ clip(p) performs two-dimensional clipping on a plot, p, from
    ++ the domain \spadtype{Plot} for the graph of one variable,
    ++ \spad{y = f(x)}; the default parameters \spad{1/4} for the fraction
    ++ and \spad{5/1} for the scale are used in the \spadfun{clip} function.
  clip: (PLOT,RN,RN) -> CLIPPED
    ++ clip(p,frac,sc) performs two-dimensional clipping on a plot, p,

```

```

++ from the domain \spadtype{Plot} for the graph of one variable
++ \spad{y = f(x)}; the fraction parameter is specified by \spad{frac}
++ and the scale parameter is specified by \spad{sc} for use in the
++ \spadfun{clip} function.
clipParametric: PLOT -> CLIPPED
++ clipParametric(p) performs two-dimensional clipping on a plot,
++ p, from the domain \spadtype{Plot} for the parametric curve
++ \spad{x = f(t)}, \spad{y = g(t)}; the default parameters \spad{1/2}
++ for the fraction and \spad{5/1} for the scale are used in the
++ \fakeAxiomFun{iClipParametric} subroutine, which is called by this
++ function.
clipParametric: (PLOT,RN,RN) -> CLIPPED
++ clipParametric(p,frac,sc) performs two-dimensional clipping on a
++ plot, p, from the domain \spadtype{Plot} for the parametric curve
++ \spad{x = f(t)}, \spad{y = g(t)}; the fraction parameter is
++ specified by \spad{frac} and the scale parameter is specified
++ by \spad{sc} for use in the \fakeAxiomFun{iClipParametric} subroutine,
++ which is called by this function.
clipWithRanges: (L L Pt,SF,SF,SF,SF) -> CLIPPED
++ clipWithRanges(pointLists,xMin,xMax,yMin,yMax) performs clipping
++ on a list of lists of points, \spad{pointLists}. Clipping is
++ done within the specified ranges of \spad{xMin}, \spad{xMax} and
++ \spad{yMin}, \spad{yMax}. This function is used internally by
++ the \fakeAxiomFun{iClipParametric} subroutine in this package.
clip: L Pt -> CLIPPED
++ clip(l) performs two-dimensional clipping on a curve l, which is
++ a list of points; the default parameters \spad{1/2} for the
++ fraction and \spad{5/1} for the scale are used in the
++ \fakeAxiomFun{iClipParametric} subroutine, which is called by this
++ function.
clip: L L Pt -> CLIPPED
++ clip(ll) performs two-dimensional clipping on a list of lists
++ of points, \spad{ll}; the default parameters \spad{1/2} for
++ the fraction and \spad{5/1} for the scale are used in the
++ \fakeAxiomFun{iClipParametric} subroutine, which is called by this
++ function.

++ Description:
++ UnivariatePolynomialDecompositionPackage implements
++ functional decomposition of univariate polynomial with coefficients
++ in an \spad{IntegralDomain} of \spad{CharacteristicZero}.

UnivariatePolynomialDecompositionPackage(R,UP): Exports == Implementation where
  R : Join(IntegralDomain,CharacteristicZero)
  UP : UnivariatePolynomialCategory(R)
  N ==> NonNegativeInteger
  LR ==> Record(left: UP, right: UP)
  QR ==> Record(quotient: UP, remainder: UP)

Exports ==> with

  monicRightFactorIfCan: (UP,N) -> Union(UP,"failed")
    ++ monicRightFactorIfCan(f,d) returns a candidate to be the
    ++ monic right factor (h in  $f = g \circ h$ ) of degree d of a
    ++ functional decomposition of the polynomial f or
    ++ \spad{"failed"} if no such candidate.
  rightFactorIfCan: (UP,N,R) -> Union(UP,"failed")
    ++ rightFactorIfCan(f,d,c) returns a candidate to be the
    ++ right factor (h in  $f = g \circ h$ ) of degree d with leading
    ++ coefficient c of a functional decomposition of the
    ++ polynomial f or \spad{"failed"} if no such candidate.
  leftFactorIfCan: (UP,UP) -> Union(UP,"failed")
    ++ leftFactorIfCan(f,h) returns the left factor (g in  $f = g \circ h$ )
    ++ of the functional decomposition of the polynomial f with
    ++ given h or \spad{"failed"} if g does not exist.
```

```

monicDecomposeIfCan: UP -> Union(LR,"failed")
  ++ monicDecomposeIfCan(f) returns a functional decomposition
  ++ of the monic polynomial f of "failed" if it has not found any.
monicCompleteDecompose: UP -> List UP
  ++ monicCompleteDecompose(f) returns a list of factors of f for
  ++ the functional decomposition ([ f1, ..., fn ] means
  ++ f = f1 o ... o fn).

```

Implementation ==> add

UnivariatePolynomialSquareFree examples
=====

```

This package provides for square-free decomposition of univariate polynomials over arbitrary rings, i.e. a partial factorization such that each factor is a product of irreducibles with multiplicity one and the factors are pairwise relatively prime. If the ring has characteristic zero, the result is guaranteed to satisfy this condition. If the ring is an infinite ring of finite characteristic, then it may not be possible to decide when polynomials contain factors which are  $p$ th powers. In this case, the flag associated with that polynomial is set to "nil" (meaning that that polynomials are not guaranteed to be square-free).

Exports ==> with

  pointColorDefault : () -> PAL
  ++ pointColorDefault() returns the default color of points in a 2D
  ++ viewport.

  pointColorDefault : PAL -> PAL
  ++ pointColorDefault(p) sets the default color of points in a 2D viewport
  ++ to the palette p.

  lineColorDefault : () -> PAL
  ++ lineColorDefault() returns the default color of lines connecting
  ++ points in a 2D viewport.

  lineColorDefault : PAL -> PAL
  ++ lineColorDefault(p) sets the default color of lines connecting points
  ++ in a 2D viewport to the palette p.

  axesColorDefault : () -> PAL
  ++ axesColorDefault() returns the default color of the axes in a
  ++ 2D viewport.

  axesColorDefault : PAL -> PAL
  ++ axesColorDefault(p) sets the default color of the axes in a 2D

```

```

++ viewport to the palette p.

unitsColorDefault    : ()                                -> PAL
++ unitsColorDefault() returns the default color of the unit ticks in
++ a 2D viewport.

unitsColorDefault    : PAL                                -> PAL
++ unitsColorDefault(p) sets the default color of the unit ticks in
++ a 2D viewport to the palette p.

pointSizeDefault     : ()                                -> PI
++ pointSizeDefault() returns the default size of the points in
++ a 2D viewport.

pointSizeDefault     : PI                                -> PI
++ pointSizeDefault(i) sets the default size of the points in a 2D
++ viewport to i.

viewPosDefault       : () -> L NNI
++ viewPosDefault() returns the default x and y position of a
++ viewport window unless overridden explicitly, newly created
++ viewports will have this x and y coordinate.

viewPosDefault       : L NNI -> L NNI
++ viewPosDefault([x,y]) sets the default x and y position of a
++ viewport window unless overridden explicitly, newly created
++ viewports will have the x and y coordinates x, y.

viewSizeDefault      : () -> L PI
++ viewSizeDefault() returns the default viewport width and height.

viewSizeDefault      : L PI -> L PI
++ viewSizeDefault([w,h]) sets the default viewport width to w and height
++ to h.

viewDefaults         : ()                                -> Void
++ viewDefaults() resets all the default graphics settings.

viewWriteDefault     : ()                                -> L S
++ viewWriteDefault() returns the list of things to write in a viewport
++ data file; a viewalone file is always generated.

viewWriteDefault     : L S                                -> L S
++ viewWriteDefault(l) sets the default list of things to write in a
++ viewport data file to the strings in l; a viewalone file is always
++ generated.

viewWriteAvailable   : ()                                -> L S
++ viewWriteAvailable() returns a list of available methods for writing,
++ such as BITMAP, POSTSCRIPT, etc.

```

```

var1StepsDefault      : () -> PI
++ var1StepsDefault() is the current setting for the number of steps to
++ take when creating a 3D mesh in the direction of the first defined
++ free variable (a free variable is considered defined when its
++ range is specified (e.g. x=0..10)).

var2StepsDefault      : () -> PI
++ var2StepsDefault() is the current setting for the number of steps to
++ take when creating a 3D mesh in the direction of the first defined
++ free variable (a free variable is considered defined when its
++ range is specified (e.g. x=0..10)).

var1StepsDefault      : PI -> PI
++ var1StepsDefault(i) sets the number of steps to take when creating a
++ 3D mesh in the direction of the first defined free variable to i
++ (a free variable is considered defined when its range is specified
++ (e.g. x=0..10)).

var2StepsDefault      : PI -> PI
++ var2StepsDefault(i) sets the number of steps to take when creating a
++ 3D mesh in the direction of the first defined free variable to i
++ (a free variable is considered defined when its range is specified
++ (e.g. x=0..10)).

tubePointsDefault     : PI -> PI
++ tubePointsDefault(i) sets the number of points to use when creating
++ the circle to be used in creating a 3D tube plot to i.

tubePointsDefault     : () -> PI
++ tubePointsDefault() returns the number of points to be used when
++ creating the circle to be used in creating a 3D tube plot.

tubeRadiusDefault     : Float -> SF  -- current tube.spad asks for SF
++ tubeRadiusDefault(r) sets the default radius for a 3D tube plot to r.

tubeRadiusDefault     : () -> SF
++ tubeRadiusDefault() returns the radius used for a 3D tube plot.

This package implements the Weierstrass preparation theorem for multivariate power series.

weierstrass(v,p) where v is a variable, and p is a TaylorSeries(R) in

which the terms of lowest degree  $s$  must include  $c*v**s$  where  $c$  is a constant,  $s>0$ , is a list of TaylorSeries coefficients  $A[i]$  of the equivalent polynomial

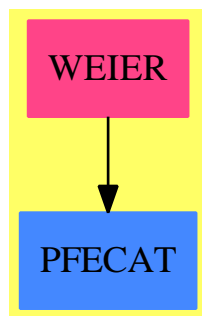

$$A = A[0] + A[1]*v + A[2]*v**2 + \dots + A[s-1]*v**(s-1) + v**s$$

such that  $p=A*B$ ,  $B$  being a TaylorSeries of minimum degree 0

ZeroDimensionalSolvePackage examples

=====

A package for computing symbolically the complex and real roots of zero-dimensional algebraic systems over the integer or rational numbers. Complex roots are given by means of univariate representations of irreducible regular chains. Real roots are given by means of tuples of coordinates lying in the RealClosure of the coefficient ring.

This constructor takes three arguments. The first one R is the coefficient ring. The second one ls is the list of variables involved in the systems to solve. The third one must be concat(ls,s) where s is an additional symbol used for the univariate representations.

WARNING. The third argument is not checked.

All operations are based on triangular decompositions. The default is to compute these decompositions directly from the input system by using the RegularChain domain constructor.

The lexTriangular algorithm can also be used for computing these decompositions (see LexTriangularPackage package constructor).

For that purpose, the operations univariateSolve, realSolve and positiveSolve admit an optional argument.

The ZeroDimensionalSolvePackage package constructor provides operations for computing symbolically the complex or real roots of zero-dimensional algebraic systems.

The package provides no multiplicity information (i.e. some returned

roots may be double or higher) but only distinct roots are returned.

Complex roots are given by means of univariate representations of irreducible regular chains. These representations are computed by the `univariateSolve` operation (by calling the `InternalRationalUnivariateRepresentationPackage` package constructor which does the job).

Real roots are given by means of tuples of coordinates lying in the `RealClosure` of the coefficient ring. They are computed by the `realSolve` and `positiveSolve` operations. The former computes all the solutions of the input system with real coordinates whereas the later concentrate on the solutions with (strictly) positive coordinates. In both cases, the computations are performed by the `RealClosure` constructor.

Both computations of complex roots and real roots rely on triangular decompositions. These decompositions can be computed in two different ways. First, by applying the `zeroSetSplit` operation from the `REGSET` domain constructor. In that case, no Groebner bases are computed. This strategy is used by default. Secondly, by applying the `zeroSetSplit` from `LEXTRIPK`. To use this later strategy with the operations `univariateSolve`, `realSolve` and `positiveSolve` one just needs to use an extra boolean argument.

Note that the way of understanding triangular decompositions is detailed in the example of the `RegularTriangularSet` constructor.

The `ZeroDimensionalSolvePackage` constructor takes three arguments. The first one `R` is the coefficient ring; it must belong to the categories `OrderedRing`, `EuclideanDomain`, `CharacteristicZero` and `RealConstant`. This means essentially that `R` is `Integer` or `Fraction(Integer)`. The second argument `ls` is the list of variables involved in the systems to solve. The third one `MUST BE concat(ls,s)` where `s` is an additional symbol used for the univariate representations. The abbreviation for `ZeroDimensionalSolvePackage` is `ZDSOLVE`.

We illustrate now how to use the constructor `ZDSOLVE` by two examples: the Arnborg and Lazard system and the L-3 system (Aubry and Moreno Maza). Note that the use of this package is also demonstrated in the example of the `LexTriangularPackage` constructor.

Define the coefficient ring.

```
R := Integer
Integer
                                Type: Domain
```

Define the lists of variables:

```
ls : List Symbol := [x,y,z,t]
```

```
[x,y,z,t]
```

```
Type: List Symbol
```

```
and:
```

```
ls2 : List Symbol := [x,y,z,t,new()$Symbol]
      [x,y,z,t,%A]
```

```
Type: List Symbol
```

```
Call the package:
```

```
pack := ZDSOLVE(R,ls,ls2)
      ZeroDimensionalSolvePackage(Integer,[x,y,z,t],[x,y,z,t,%A])
      Type: Domain
```

```
Define a polynomial system (Arnborg-Lazard)
```

```
p1 := x**2*y*z + x*y**2*z + x*y*z**2 + x*y*z + x*y + x*z + y*z
      2      2      2
      x y z + (x y + (x + x + 1)y + x)z + x y
      Type: Polynomial Integer
```

```
p2 := x**2*y**2*z + x*y**2*z**2 + x**2*y*z + x*y*z + y*z + x + z
      2 2      2 2      2
      x y z + (x y + (x + x + 1)y + 1)z + x
      Type: Polynomial Integer
```

```
p3 := x**2*y**2*z**2 + x**2*y**2*z + x*y**2*z + x*y*z + x*z + z + 1
      2 2 2      2      2
      x y z + ((x + x)y + x y + x + 1)z + 1
      Type: Polynomial Integer
```

```
lp := [p1, p2, p3]
      2      2      2
      [x y z + (x y + (x + x + 1)y + x)z + x y,
      2 2      2 2      2
      x y z + (x y + (x + x + 1)y + 1)z + x,
      2 2 2      2      2
      x y z + ((x + x)y + x y + x + 1)z + 1]
      Type: List Polynomial Integer
```

Note that these polynomials do not involve the variable t; we will use it in the second example.

First compute a decomposition into regular chains (i.e. regular triangular sets).

```
triangSolve(lp)$pack
[
{
```

```

]
Type: List RegularChain(Integer,[x,y,z,t])

```

We can see easily from this decomposition (consisting of a single regular chain) that the input system has 20 complex roots.

Then we compute a univariate representation of this regular chain.

```

univariateSolve(lp)$pack
[

```

```

Type: List Record(complexRoots: SparseUnivariatePolynomial Integer,
coordinates: List Polynomial Integer)

```

We see that the zeros of our regular chain are split into three components. This is due to the use of univariate polynomial factorization.

Each of these components consist of two parts. The first one is an irreducible univariate polynomial  $p(?)$  which defines a simple algebraic extension of the field of fractions of  $R$ . The second one consists of multivariate polynomials  $\text{pol1}(x,\%A)$ ,  $\text{pol2}(y,\%A)$  and  $\text{pol3}(z,\%A)$ . Each of these polynomials involve two variables: one is an indeterminate  $x$ ,  $y$  or  $z$  of the input system  $lp$  and the other is  $\%A$  which represents any root of  $p(?)$ . Recall that this  $\%A$  is the last element of the third parameter of ZDSOLVE. Thus any complex root  $?$  of  $p(?)$  leads to a solution of the input system  $lp$  by replacing  $\%A$  by this  $?$  in  $\text{pol1}(x,\%A)$ ,  $\text{pol2}(y,\%A)$  and  $\text{pol3}(z,\%A)$ . Note that the polynomials  $\text{pol1}(x,\%A)$ ,  $\text{pol2}(y,\%A)$  and  $\text{pol3}(z,\%A)$  have degree one w.r.t.  $x$ ,  $y$  or  $z$  respectively. This is always the case for all

univariate representations. Hence the operation `univariateSolve` replaces a system of multivariate polynomials by a list of univariate polynomials, what justifies its name. Another example of univariate representations illustrates the `LexTriangularPackage` package constructor.

We now compute the solutions with real coordinates:

```

Type: List List RealClosure Fraction Integer

The number of real solutions for the input system is:

# 1r

8

Type: PositiveInteger

Each of these real solutions is given by a list of elements in `RealClosure(R)`. In these 8 lists, the first element is a value of  $z$ , the second of  $y$  and the last of  $x$ . This is logical since by setting the list of variables of the package to  $[x,y,z,t]$  we mean that the elimination ordering on the variables is  $t < z < y < x$ . Note that each system treated by the ZDSOLVE package constructor needs only to be zero-dimensional w.r.t. the variables involved in the system it-self and not necessarily w.r.t. all the variables used to define the package.

We can approximate these real numbers as follows. This computation takes between 30 sec. and 5 min, depending on your machine.

```
[ [approximate(r,1/1000000) for r in point] for point in lr]

]
]

```

Type: List List Fraction Integer

We can also concentrate on the solutions with real (strictly) positive coordinates:

```
lpr := positiveSolve(lp)$pack
[]
```

Type: List List RealClosure Fraction Integer

Thus we have checked that the input system has no solution with strictly positive coordinates.

Let us define another polynomial system (L-3).

```
f0 := x**3 + y + z + t- 1
      3
      z + y + x  + t - 1
      Type: Polynomial Integer

f1 := x + y**3 + z + t -1
      3
      z + y  + x + t - 1
      Type: Polynomial Integer

f2 := x + y + z**3 + t-1
      3
      z  + y + x + t - 1
      Type: Polynomial Integer

f3 := x + y + z + t**3 -1
      3
      z + y + x + t  - 1
      Type: Polynomial Integer

lf := [f0, f1, f2, f3]
      3      3      3      3
[z + y + x  + t - 1, z + y  + x + t - 1, z  + y + x + t - 1, z + y + x + t  - 1]
      Type: List Polynomial Integer
```

First compute a decomposition into regular chains (i.e. regular triangular sets).

```
lts := triangSolve(lf)$pack

Type: List Record(complexRoots: SparseUnivariatePolynomial Integer,

```

coordinates: List Polynomial Integer)

Note that this computation is made from the input system lf.

However it is possible to reuse a pre-computed regular chain as follows:

```
ts := lts.1
      2      3      3
{t  + t + 1, z  - z - t  + t,

      3      2      2      3      6      3      3      2
(3z + 3t  - 3)y  + (3z  + (6t  - 6)z + 3t  - 6t  + 3)y + (3t  - 3)z
+
      6      3      9      6      3
(3t  - 6t  + 3)z + t  - 3t  + 5t  - 3t
,
x + y + z}

Type: RegularChain(Integer,[x,y,z,t])

    3      3      3      3      3

```

Type: List List RealClosure Fraction Integer

The number of real solutions for the input system is:

```

#lr2
27

```

Type: PositiveInteger

Another example of computation of real solutions illustrates the LexTriangularPackage package constructor.

We concentrate now on the solutions with real (strictly) positive

coordinates:

```
lpr2 := positiveSolve(lf)$pack
      1      3      1      1      3      1      1      3      1
      [[%B40,- - %B40 + -, - %B40 + -, - %B40 + -]]
      3      3      3      3      3      3      3
Type: List List RealClosure Fraction Integer
```

Finally, we approximate the coordinates of this point with 20 exact digits:

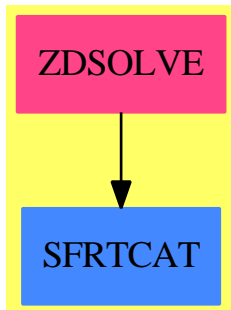

```
[approximate(r,1/10**21)::Float for r in lpr2.1]
[0.3221853546 2608559291, 0.3221853546 2608559291, 0.3221853546 2608559291,
 0.3221853546 2608559291]
Type: List Float
```

## ZeroDimensionalSolvePackage (ZDSOLVE)

### Exports:

convert positiveSolve realSolve squareFree triangSolve univariateSolve

— package ZDSOLVE ZeroDimensionalSolvePackage —

```
)abbrev package ZDSOLVE ZeroDimensionalSolvePackage
++ Author: Marc Moreno Maza
++ Date Created: 23/01/1999
++ Date Last Updated: 08/02/1999
++ Description:
++ A package for computing symbolically the complex and real roots of
```

```

++ zero-dimensional algebraic systems over the integer or rational
++ numbers. Complex roots are given by means of univariate representations
++ of irreducible regular chains. Real roots are given by means of tuples
++ of coordinates lying in the \spadtype{RealClosure} of the coefficient ring.
++ This constructor takes three arguments. The first one \spad{R} is the
++ coefficient ring. The second one \spad{ls} is the list of variables
++ involved in the systems to solve. The third one must be \spad{concat(ls,s)}
++ where \spad{s} is an additional symbol used for the univariate
++ representations.
++ WARNING. The third argument is not checked.
++ All operations are based on triangular decompositions.
++ The default is to compute these decompositions directly from the input
++ system by using the \spadtype{RegularChain} domain constructor.
++ The lexTriangular algorithm can also be used for computing these
++ decompositions (see \spadtype{LexTriangularPackage} package constructor).
++ For that purpose, the operations univariateSolve, realSolve and
++ positiveSolve admit an optional argument.

```

```

Exports == with
  triangSolve: (LP,B,B) -> List RegularChain(R,ls)
    ++ \spad{triangSolve(lp,info?,lextri?)}} decomposes the variety
    ++ associated with \axiom{lp} into regular chains.
    ++ Thus a point belongs to this variety iff it is a regular
    ++ zero of a regular set in in the output.
    ++ Note that \axiom{lp} needs to generate a zero-dimensional ideal.
    ++ If \axiom{lp} is not zero-dimensional then the result is only
    ++ a decomposition of its zero-set in the sense of the closure
    ++ (w.r.t. Zarisky topology).
    ++ Moreover, if \spad{info?} is \spad{true} then some information is
    ++ displayed during the computations.
    ++ See zeroSetSplit from RegularTriangularSetCategory(lp,true,info?).
    ++ If \spad{lextri?} is \spad{true} then the lexTriangular algorithm
    ++ is called
    ++ from the \spadtype{LexTriangularPackage} constructor
    ++ (see zeroSetSplit from LexTriangularPackage(lp,false)).
    ++ Otherwise, the triangular decomposition is computed directly from
    ++ the input
    ++ system by using the zeroSetSplit from RegularChain
  triangSolve: (LP,B) -> List RegularChain(R,ls)
    ++ \spad{triangSolve(lp,info?)}} returns the same as
    ++ \spad{triangSolve(lp,false)}
  triangSolve: LP -> List RegularChain(R,ls)
    ++ \spad{triangSolve(lp)} returns the same as
    ++ \spad{triangSolve(lp,false,false)}
  univariateSolve: RegularChain(R,ls) -> _
    List Record(complexRoots: U, coordinates: LP)
    ++ \spad{univariateSolve(ts)} returns a univariate representation
    ++ of \spad{ts}.
    ++ See rur from RationalUnivariateRepresentationPackage(lp,true).
  univariateSolve: (LP,B,B,B) -> List RUR
    ++ \spad{univariateSolve(lp,info?,check?,lextri?)}} returns a univariate
    ++ representation of the variety associated with \spad{lp}.
    ++ Moreover, if \spad{info?} is \spad{true} then some information is
    ++ displayed during the decomposition into regular chains.
    ++ If \spad{check?} is \spad{true} then the result is checked.
    ++ See rur from RationalUnivariateRepresentationPackage(lp,true).
    ++ If \spad{lextri?} is \spad{true} then the lexTriangular
    ++ algorithm is called
    ++ from the \spadtype{LexTriangularPackage} constructor

++ \spad{realSolve(ts,info?,check?)} returns the same as
++ \spad{realSolve(ts,info?,check?,false)}.
realSolve: (LP,B) -> List REALSOL
++ \spad{realSolve(ts,info?)} returns the same as
++ \spad{realSolve(ts,info?,false,false)}.
realSolve: LP -> List REALSOL
++ \spad{realSolve(lp)} returns the same as
++ \spad{realSolve(ts,false,false,false)}
positiveSolve: RegularChain(R,ls) -> List REALSOL
++ \spad{positiveSolve(ts)} returns the points of the regular
++ set of \spad{ts} with (real) strictly positive coordinates.
positiveSolve: (LP,B,B) -> List REALSOL
++ \spad{positiveSolve(lp,info?,lextri?)} returns the set of the points
++ in the variety associated with \spad{lp} whose coordinates are
++ (real) strictly positive.
++ Moreover, if \spad{info?} is \spad{true} then some information is
++ displayed during decomposition into regular chains.
++ If \spad{lextri?} is \spad{true} then the lexTriangular
++ algorithm is called
++ from the \spadtype{LexTriangularPackage} constructor
++ (see zeroSetSplit from LexTriangularPackage(lp,false)).
++ Otherwise, the triangular decomposition is computed directly

```

```

++ from the input
++ system by using the zeroSetSplit from \spadtype{RegularChain}.
++ WARNING. For each set of coordinates given by
++ \spad{positiveSolve(lp,info?,lextri?)}}
++ the ordering of the indeterminates is reversed w.r.t. \spad{ls}.
positiveSolve: (LP,B) -> List REALSOL
++ \spad{positiveSolve(lp)} returns the same as
++ \spad{positiveSolve(lp,info?,false)}}.
positiveSolve: LP -> List REALSOL
++ \spad{positiveSolve(lp)} returns the same as
++ \spad{positiveSolve(lp,false,false)}}.
squareFree: (TS) -> List ST
++ \spad{squareFree(ts)} returns the square-free factorization
++ of \spad{ts}. Moreover, each factor is a Lazard triangular set
++ and the decomposition
++ is a Kalkbrener split of \spad{ts}, which is enough here for
++ the matter of solving zero-dimensional algebraic systems.
++ WARNING. \spad{ts} is not checked to be zero-dimensional.
convert: Q -> Q2
++ \spad{convert(q)} converts \spad{q}.
convert: P -> PRC
++ \spad{convert(p)} converts \spad{p}.
convert: Q2 -> PRC
++ \spad{convert(q)} converts \spad{q}.
convert: U -> URC
++ \spad{convert(u)} converts \spad{u}.
convert: ST -> List Q2
++ \spad{convert(st)} returns the members of \spad{st}.
