On entry: the initial value of the independent variable x. Constraint: X /= XEND. On exit: if g is supplied by the user, it contains the point where g(x,y)=0.0, unless g(x,y)/=0.0 anywhere on the range X to XEND, in which case, X will contain XEND. If g is not supplied by the user it contains XEND, unless an error has occurred, when it contains the value of x at the error.

2: XEND -- DOUBLE PRECISION Input
On entry: the final value of the independent variable. If XEND < X, integration proceeds in the negative direction. Constraint: XEND /= X.

3: M -- INTEGER Input
On entry: the first dimension of the array RESULT. This will usually be equal to the number of points at which the solution is required.
Constraint: M > 0.

4: N -- INTEGER Input
On entry: the number of differential equations.
Constraint: N >= 1.

5: Y(N) -- DOUBLE PRECISION array Input/Output
On entry: the initial values of the solution $y_1,y_2,...,y_n$ at x = X. On exit: the computed values of the solution at the final point x = X.

6: FCN -- SUBROUTINE, supplied by the user.
External Procedure
FCN must evaluate the functions f_i (i.e., the derivatives y') for given values of their arguments x,y ,y ,...,y .

```
  i                                         1  2      n

Its specification is:

       SUBROUTINE FCN (X, Y, F)
       DOUBLE PRECISION X, Y(n), F(n)
where n is the actual value of N in the call of D02CJF.

 1:  X -- DOUBLE PRECISION                             Input
     On entry: the value of the independent variable x.

 2:  Y(*) -- DOUBLE PRECISION array                    Input
     On entry: the value of the variable y , for
                                          i
     i=1,2,...,n.

 3:  F(*) -- DOUBLE PRECISION array                   Output
     On exit: the value of f , for i=1,2,...,n.
                            i
FCN must be declared as EXTERNAL in the (sub)program
from which D02CJF is called. Parameters denoted as
Input must not be changed by this procedure.

7:  TOL -- DOUBLE PRECISION                           Input
    On entry: a positive tolerance for controlling the error in
    the integration. Hence TOL affects the determination of the
    position where g(x,y)=0.0, if g is supplied.

    D02CJF has been designed so that, for most problems, a
    reduction in TOL leads to an approximately proportional
    reduction in the error in the solution. However, the actual
    relation between TOL and the accuracy achieved cannot be
    guaranteed. The user is strongly recommended to call D02CJF
    with more than one value for TOL and to compare the results
    obtained to estimate their accuracy. In the absence of any
    prior knowledge, the user might compare the results obtained
                                   -p             -p-1
    by calling D02CJF with TOL=10.0   and TOL=10.0     where p
    correct decimal digits are required in the solution.
    Constraint: TOL > 0.0.

8:  RELABS -- CHARACTER*1                             Input
    On entry: the type of error control. At each step in the
    numerical solution an estimate of the local error, EST, is
    made. For the current step to be accepted the following
    condition must be satisfied:

                 ------------------------------
                / n
               /  --                          2
       EST=   /   >  (e /((tau) *|y |+(tau) )) <=1.0
```

```
              /    --   i       r   i       a
            \/     i=1
where (tau)  and (tau)  are defined by
           r         a
     RELABS   (tau)    (tau)
                   r        a

     'M'      TOL      TOL

     'A'      0.0      TOL

     'R'      TOL      (epsilon)

     'D'      TOL      TOL
where (epsilon) is a small machine-dependent number and e
                                                         i
is an estimate of the local error at y , computed
                                      i
internally. If the appropriate condition is not satisfied,
the step size is reduced and the solution is recomputed on
the current step. If the user wishes to measure the error in
the computed solution in terms of the number of correct
decimal places, then RELABS should be set to 'A' on entry,
whereas if the error requirement is in terms of the number
of correct significant digits, then RELABS should be set to
'R'. If the user prefers a mixed error test, then RELABS
should be set to 'M', otherwise if the user has no
preference, RELABS should be set to the default 'D'. Note
that in this case 'D' is taken to be 'M'. Constraint: RELABS
= 'M', 'A', 'R', 'D'.

 9:  RESULT(M,N) -- DOUBLE PRECISION array                Output
     On exit: the computed values of the solution at the points
     given by OUTPUT.

10:  OUTPUT -- SUBROUTINE, supplied by the user.
                                              External Procedure
     OUTPUT allows the user to have access to intermediate values
     of the computed solution at successive points specified by the
     user. These solution values may be returned to the user via
     the array RESULT if desired (this is a non-standard feature
     added for use with the Axiom system).  OUTPUT is initially
     called by D02CJF with XSOL = X (the initial value of x). The
     user must reset XSOL to the next point where OUTPUT is to be
     called, and so on at each call to OUTPUT. If, after a call
     to OUTPUT, the reset point XSOL is beyond XEND, D02CJF will
     integrate to XEND with no further calls to OUTPUT; if a call
     to OUTPUT is required at the point XSOL = XEND, then XSOL
     must be given precisely the value XEND.
```

```
Its specification is:

     SUBROUTINE OUTPUT(XSOL,Y,COUNT,M,N,RESULT)
     DOUBLE PRECISION Y(N),RESULT(M,N),XSOL
     INTEGER M,N,COUNT

 1:  XSOL -- DOUBLE PRECISION                   Input/Output
     On entry: the current value of the independent
     variable x. On exit: the next value of x at which
     OUTPUT is to be called.

 2:  Y(N) -- DOUBLE PRECISION array                    Input
     On entry: the computed solution at the point XSOL.

 3:  COUNT -- INTEGER                           Input/Output
     On entry: Zero if OUTPUT has not been called before, or
     the previous value of COUNT.
     On exit: A new value of COUNT: this can be used to keep
     track of the number of times OUTPUT has been called.

 4:  M -- INTEGER                                      Input
     On entry: The first dimension of RESULT.

 5:  N -- INTEGER                                      Input
     On entry: The dimension of Y.

 6:  RESULT(M,N) -- DOUBLE PRECISION array      Input/Output
     On entry: the previous contents of RESULT.
     On exit: RESULT may be used to return the values of the
     intermediate solutions to the user.

OUTPUT must be declared as EXTERNAL in the (sub)program
from which D02CJF is called. Parameters denoted as
Input must not be changed by this procedure.

11:  G -- DOUBLE PRECISION FUNCTION, supplied by the user.
                                          External Procedure
     G must evaluate the function g(x,y) for specified values x,y
     . It specifies the function g for which the first position x
     where g(x,y)=0 is to be found.

     If the user does not require the root finding option, the
     actual argument G  mustbe the dummy routine D02CJW. (D02CJW
     is included in the NAG Foundation Library and so need not be
     supplied by the user).

     Its specification is:

          DOUBLE PRECISION FUNCTION G (X, Y)
          DOUBLE PRECISION X, Y(n)
where n is the actual value of N in the call of D02CJF.

 1:  X -- DOUBLE PRECISION                             Input
     On entry: the value of the independent variable x.

 2:  Y(*) -- DOUBLE PRECISION array                    Input
     On entry: the value of the variable y , for
                                           i
     i=1,2,...,n.
G must be declared as EXTERNAL in the (sub)program from
which D02CJF is called. Parameters denoted as Input
must not be changed by this procedure.

12:  W(28+21*N) -- DOUBLE PRECISION array               Workspace

13:  IFAIL -- INTEGER                                Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry TOL <= 0.0,

or       N <= 0,

or       RELABS /= 'M', 'A', 'R' or 'D'.

or       X = XEND.

IFAIL= 2
With the given value of TOL, no further progress can be made
across the integration range from the current point x = X.
(See Section 8 for a discussion of this error exit.) The
components Y(1),Y(2),...,Y(N) contain the computed values of
the solution at the current point x = X. If the user has
supplied g, then no point at which g(x,y) changes sign has
been located up to the point x = X.

IFAIL= 3
TOL is too small for D02CJF to take an initial step. X and Y
(1),Y(2),...,Y(N) retain their initial values.

IFAIL= 4
XSOL has not been reset or XSOL lies behind X in the
direction of integration, after the initial call to OUTPUT,
if the OUTPUT option was selected.

IFAIL= 5
A value of XSOL returned by OUTPUT has not been reset or
lies behind the last value of XSOL in the direction of
integration, if the OUTPUT option was selected.

IFAIL= 6
At no point in the range X to XEND did the function g(x,y)
change sign, if g was supplied. It is assumed that g(x,y)=0
has no solution.

IFAIL= 7
A serious error has occurred in an internal call. Check all
subroutine calls and array sizes. Seek expert help.

7. Accuracy

The accuracy of the computation of the solution vector Y may be
controlled by varying the local error tolerance TOL. In general,
a decrease in local error tolerance should lead to an increase in
accuracy. Users are advised to choose RELABS = 'M' unless they
have a good reason for a different choice.

If the problem is a root-finding one, then the accuracy of the
root determined will depend on the properties of g(x,y). The user
should try to code G without introducing any unnecessary
cancellation errors.

8. Further Comments

If more than one root is required then D02QFF(*) should be used.

If the routine fails with IFAIL = 3, then it can be called again
with a larger value of TOL if this has not already been tried. If
the accuracy requested is really needed and cannot be obtained
with this routine, the system may be very stiff (see below) or so
badly scaled that it cannot be solved to the required accuracy.

If the routine fails with IFAIL = 2, it is probable that it has
been called with a value of TOL which is so small that a solution
cannot be obtained on the range X to XEND. This can happen for
well-behaved systems and very small values of TOL. The user
should, however, consider whether there is a more fundamental
difficulty. For example:
(a)   in the region of a singularity (infinite value) of the
     solution, the routine will usually stop with IFAIL = 2,
     unless overflow occurs first. Numerical integration cannot
     be continued through a singularity, and analytic treatment
     should be considered;

(b)   for 'stiff' equations where the solution contains rapidly
     decaying components, the routine will use very small steps
     in x (internally to D02CJF) to preserve stability. This
     will exhibit itself by making the computing time
     excessively long, or occasionally by an exit with IFAIL =
     2. Adams methods are not efficient in such cases, and the
     user should try D02EJF.

9. Example

We illustrate the solution of four different problems. In each
case the differential system (for a projectile) is

                         y'=tan(phi)

                    -0.032tan(phi)   0.02v
                v'= --------------- --------
                          v         cos(phi)

                              -0.032
                       (phi)'= ------
                                 2
                                v

over an interval X = 0.0 to XEND = 10.0 starting with values
y=0.5, v=0.5 and (phi)=(pi)/5. We solve each of the following
problems with local error tolerances 1.0E-4 and 1.0E-5.

(i)   To integrate to x=10.0 producing output at intervals of 2.0
     until a point is encountered where y=0.0.

(ii)  As (i) but with no intermediate output.

(iii) As (i) but with no termination on a root-finding condition.

(iv)  As (i) but with no intermediate output and no root-finding
     termination condition.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

     D02EJF(3NAG)                D02EJF                D02EJF(3NAG)

     D02 -- Ordinary Differential Equations                  D02EJF
             D02EJF -- NAG Foundation Library Routine Document

     Note: Before using this routine, please read the Users' Note for
     your implementation to check implementation-dependent details.
     The symbol (*) after a NAG routine name denotes a routine that is
     not included in the Foundation Library.

     Note for users via the Axiom system: the interface to this routine
     has been enhanced for use with Axiom and is slightly different to
     that offered in the standard version of the Foundation Library.

     1. Purpose

     D02EJF integrates a stiff system of first-order ordinary
     differential equations over an interval with suitable initial
     conditions, using a variable-order, variable-step method
     implementing the Backward Differentiation Formulae (BDF), until a
     user-specified function, if supplied, of the solution is zero,
     and returns the solution at points specified by the user, if
     desired.

     2. Specification

            SUBROUTINE D02EJF (X, XEND, M, N, Y, FCN, PEDERV, TOL,
           1                   RELABS, OUTPUT, G, W, IW, RESULT, IFAIL)
            INTEGER          M, N, IW, IFAIL
            DOUBLE PRECISION X, XEND, Y(N), TOL, G, W(IW), RESULT(M,N)
            CHARACTER*1      RELABS
```

```
      EXTERNAL        FCN, PEDERV, OUTPUT, G
```

3. Description

The routine advances the solution of a system of ordinary differential equations

$$y'_i = f_i(x, y_1, y_2, \ldots, y_n), \quad i=1,2,\ldots,n,$$

from x = X to x = XEND using a variable-order, variable-step method implementing the BDF. The system is defined by a subroutine FCN supplied by the user, which evaluates f_i in terms of x and $y_1, y_2, \ldots, y_n$ (see Section 5). The initial values of $y_1, y_2, \ldots, y_n$ must be given at x = X.

The solution is returned via the user-supplied routine OUTPUT at points specified by the user, if desired: this solution is obtained by C^1 interpolation on solution values produced by the method. As the integration proceeds a check can be made on the user-specified function g(x,y) to determine an interval where it changes sign. The position of this sign change is then determined accurately by C^1 interpolation to the solution. It is assumed that g(x,y) is a continuous function of the variables, so that a solution of g(x,y) = 0.0 can be determined by searching for a change in sign in g(x,y). The accuracy of the integration, the interpolation and, indirectly, of the determination of the position where g(x,y) = 0.0, is controlled by the parameters TOL and RELABS. The Jacobian of the system y'=f(x,y) may be supplied in routine PEDERV, if it is available.

For a description of BDF and their practical implementation see Hall and Watt [1].

5. Parameters

1: X -- DOUBLE PRECISION Input/Output
On entry: the initial value of the independent variable x.
Constraint: X /= XEND On exit: if G is supplied by the user, X contains the point where g(x,y) = 0.0, unless g(x,y) /= 0.

```
    0 anywhere on the range X to XEND, in which case, X will
    contain XEND. If G is not supplied X contains XEND, unless
    an error has occured, when it contains the value of x at the
    error.

2:  XEND -- DOUBLE PRECISION                               Input
    On entry: the final value of the independent variable. If
    XEND < X, integration proceeds in the negative direction.
    Constraint: XEND /= X.

3:  M -- INTEGER                                           Input
    On entry: the first dimension of the array RESULT.  This
    will usually be equal to the number of points at which the
    solution is required.
    Constraint: M > 0.

4:  N -- INTEGER                                           Input
    On entry: the number of differential equations, n.
    Constraint: N >= 1.

5:  Y(N) -- DOUBLE PRECISION array                  Input/Output
    On entry: the initial values of the solution y ,y ,...,y
                                                  1  2      n
    at x = X. On exit: the computed values of the solution at
    the final point x = X.

6:  FCN -- SUBROUTINE, supplied by the user.
                                              External Procedure
    FCN must evaluate the functions f  (i.e., the derivatives
                                     i
    y' ) for given values of their arguments x,y ,y ,...,y .
      i                                         1  2      n

    Its specification is:

           SUBROUTINE FCN (X, Y, F)
           DOUBLE PRECISION X, Y(n), F(n)
    where n is the actual value of N in the call of D02EJF.

     1:  X -- DOUBLE PRECISION                             Input
         On entry: the value of the independent variable x.

     2:  Y(*) -- DOUBLE PRECISION array                    Input
         On entry: the value of the variable y , for
                                              i
         i=1,2,...,n.

     3:  F(*) -- DOUBLE PRECISION array                   Output
         On exit: the value of f , for i=1,2,...,n.
                                i
```

FCN must be declared as EXTERNAL in the (sub)program from which D02EJF is called. Parameters denoted as Input must not be changed by this procedure.

7: PEDERV -- SUBROUTINE, supplied by the user. External Procedure

PEDERV must evaluate the Jacobian of the system (that is, the partial derivatives $\frac{ddf_i}{ddy_j}$) for given values of the variables $x,y_1,y_2,\ldots,y_n$.

Its specification is:

```
       SUBROUTINE PEDERV (X, Y, PW)
       DOUBLE PRECISION X, Y(n), PW(n,n)
```

where n is the actual value of N in the call of D02EJF.

1: X -- DOUBLE PRECISION Input

On entry: the value of the independent variable x.

2: Y(*) -- DOUBLE PRECISION array Input

On entry: the value of the variable y_i, for $i=1,2,\ldots,n$.

3: PW(n,*) -- DOUBLE PRECISION array Output

On exit: the value of $\frac{ddf_i}{ddy_j}$, for $i,j=1,2,\ldots,n$.

If the user does not wish to supply the Jacobian, the actual argument PEDERV must be the dummy routine D02EJY . (D02EJY is included in the NAG Foundation Library and so need not be supplied by the user. The name may be implementation dependent: see the User's Note for your implementation for details).
PEDERV must be declared as EXTERNAL in the (sub)program from which D02EJF is called. Parameters denoted as Input must not be changed by this procedure.

8: TOL -- DOUBLE PRECISION Input/Output

On entry: TOL must be set to a positive tolerance for controlling the error in the integration. Hence TOL affects the determination of the position where g(x,y) = 0.0, if G is supplied.

D02EJF has been designed so that, for most problems, a reduction in TOL leads to an approximately proportional reduction in the error in the solution. However, the actual relation between TOL and the accuracy achieved cannot be guaranteed. The user is strongly recommended to call D02EJF with more than one value for TOL and to compare the results obtained to estimate their accuracy. In the absence of any prior knowledge, the user might compare the results obtained by calling D02EJF with $TOL=10^{-p}$ and $TOL=10^{-p-1}$ if p correct decimal digits are required in the solution. Constraint: TOL > 0.0. On exit: normally unchanged. However if the range X to XEND is so short that a small change in TOL is unlikely to make any change in the computed solution, then, on return, TOL has its sign changed.

9: RELABS -- CHARACTER*1 Input

On entry: the type of error control. At each step in the numerical solution an estimate of the local error, EST, is made. For the current step to be accepted the following condition must be satisfied:

$$EST=\sqrt{\frac{1}{n}\sum_{i=1}^{n}(e_i/((\tau)_r*|y_i|+(\tau)_a))^2}\le 1.0$$

where $(\tau)_r$ and $(\tau)_a$ are defined by

RELABS	$(\tau)_r$	$(\tau)_a$
'M'	TOL	TOL
'A'	0.0	TOL
'R'	TOL	(ϵ)
'D'	TOL	(ϵ)

where (ϵ) is a small machine-dependent number and e_i is an estimate of the local error at y_i, computed internally. If the appropriate condition is not satisfied, the step size is reduced and the solution is recomputed on the current step. If the user wishes to measure the error in the computed solution in terms of the number of correct decimal places, then RELABS should be set to 'A' on entry, whereas if the error requirement is in terms of the number

```
     of correct significant digits, then RELABS should be set to
     'R'. If the user prefers a mixed error test, then RELABS
     should be set to 'M', otherwise if the user has no
     preference, RELABS should be set to the default 'D'. Note
     that in this case 'D' is taken to be 'R'. Constraint: RELABS
     = 'A', 'M', 'R' or 'D'.

 10: OUTPUT -- SUBROUTINE, supplied by the user.
                                          External Procedure
     OUTPUT allows the user to have access to intermediate values
     of the computed solution at successive points specified by the
     user. These solution values may be returned to the user via
     the array RESULT if desired (this is a non-standard feature
     added for use with the Axiom system).  OUTPUT is initially
     called by D02EJF with XSOL = X (the initial value of x). The
     user must reset XSOL to the next point where OUTPUT is to be
     called, and so on at each call to OUTPUT. If, after a call
     to OUTPUT, the reset point XSOL is beyond XEND, D02EJF will
     integrate to XEND with no further calls to OUTPUT; if a call
     to OUTPUT is required at the point XSOL = XEND, then XSOL
     must be given precisely the value XEND.

     Its specification is:

          SUBROUTINE OUTPUT(XSOL,Y,COUNT,M,N,RESULT)
          DOUBLE PRECISION Y(N),RESULT(M,N),XSOL
          INTEGER M,N,COUNT

      1:  XSOL -- DOUBLE PRECISION                  Input/Output
          On entry: the current value of the independent
          variable x. On exit: the next value of x at which
          OUTPUT is to be called.

      2:  Y(N) -- DOUBLE PRECISION array                   Input
          On entry: the computed solution at the point XSOL.

      3:  COUNT -- INTEGER                          Input/Output
          On entry: Zero if OUTPUT has not been called before, or
          the previous value of COUNT.
          On exit: A new value of COUNT: this can be used to keep
          track of the number of times OUTPUT has been called.

      4:  M -- INTEGER                                     Input
          On entry: The first dimension of RESULT.

      5:  N -- INTEGER                                     Input
          On entry: The dimension of Y.

      6:  RESULT(M,N) -- DOUBLE PRECISION array     Input/Output
          On entry: the previous contents of RESULT.
          On exit: RESULT may be used to return the values of the
          intermediate solutions to the user.

     OUTPUT must be declared as EXTERNAL in the (sub)program
     from which D02EJF is called. Parameters denoted as
     Input must not be changed by this procedure.

 11: G -- DOUBLE PRECISION FUNCTION, supplied by the user.
                                          External Procedure
     G must evaluate the function g(x,y) for specified values x,y
     . It specifies the function g for which the first position x
     where g(x,y) = 0 is to be found.

     Its specification is:

            DOUBLE PRECISION FUNCTION G (X, Y)
            DOUBLE PRECISION X, Y(n)
     where n is the actual value of N in the call of D02EJF.

      1:  X -- DOUBLE PRECISION                         Input
          On entry: the value of the independent variable x.

      2:  Y(*) -- DOUBLE PRECISION array                Input
          On entry: the value of the variable y , for
                                                 i
          i=1,2,...,n.
     If the user does not require the root finding option,
     the actual argument G must be the dummy routine D02EJW.
     (D02EJW is included in the NAG Foundation Library and
     so need not be supplied by the user).
     G must be declared as EXTERNAL in the (sub)program from
     which D02EJF is called. Parameters denoted as Input
     must not be changed by this procedure.

 12: W(IW) -- DOUBLE PRECISION array                Workspace

 13: IW -- INTEGER                                      Input
     On entry:
     the dimension of the array W as declared in the (sub)program
     from which D02EJF is called.
     Constraint: IW>=(12+N)*N+50.

 14: RESULT(M,N) -- DOUBLE PRECISION array             Output
     On exit: the computed values of the solution at the points
     given by OUTPUT.

 15: IFAIL -- INTEGER                            Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.
     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry TOL <= 0.0,

     or       X = XEND,

     or       N <= 0,

     or       RELABS /= 'M', 'A', 'R', 'D'.

     or       IW<(12+N)*N+50.

IFAIL= 2
     With the given value of TOL, no further progress can be made
     across the integration range from the current point x = X.
     (See Section 5 for a discussion of this error test.) The
     components Y(1),Y(2),...,Y(n) contain the computed values of
     the solution at the current point x = X. If the user has
     supplied G, then no point at which g(x,y) changes sign has
     been located up to the point x = X.

IFAIL= 3
     TOL is too small for D02EJF to take an initial step. X and Y
     (1),Y(2),...,Y(n) retain their initial values.

IFAIL= 4
     XSOL lies behind X in the direction of integration, after
     the initial call to OUTPUT, if the OUTPUT option was
     selected.

IFAIL= 5
     A value of XSOL returned by OUTPUT lies behind the last
     value of XSOL in the direction of integration, if the OUTPUT
     option was selected.

IFAIL= 6
     At no point in the range X to XEND did the function g(x,y)
     change sign, if G was supplied. It is assumed that g(x,y) =
     0 has no solution.
```

IFAIL= 7
A serious error has occurred in an internal call to C05AZF(*). Check all subroutine calls and array dimensions. Seek expert help.

IFAIL= 8
A serious error has occurred in an internal call to D02XKF(*). Check all subroutine calls and array dimensions. Seek expert help.

IFAIL= 9
A serious error has occurred in an internal call to D02NMF(*). Check all subroutine calls and array dimensions. Seek expert help.

7. Accuracy

The accuracy of the computation of the solution vector Y may be controlled by varying the local error tolerance TOL. In general, a decrease in local error tolerance should lead to an increase in accuracy. Users are advised to choose RELABS = 'R' unless they have a good reason for a different choice. It is particularly appropriate if the solution decays.

If the problem is a root-finding one, then the accuracy of the root determined will depend strongly on $\frac{dg}{dx}$ and $\frac{dg}{dy_i}$, for $i=1,2,...,n$. Large values for these quantities may imply large errors in the root.

8. Further Comments

If more than one root is required, then to determine the second and later roots D02EJF may be called again starting a short distance past the previously determined roots. Alternatively the user may construct his own root finding code using D02QDF(*) (or the routines of the subchapter D02M-D02N), D02XKF(*) and C05AZF(*).

If it is easy to code, the user should supply the routine PEDERV. However, it is important to be aware that if PEDERV is coded incorrectly, a very inefficient integration may result and possibly even a failure to complete the integration (IFAIL = 2).

9. Example

We illustrate the solution of five different problems. In each case the differential system is the well-known stiff Robertson

```
     problem.

                                     4
                         a'= -0.04a-10 bc
                                     4       7 2
                         b'=  0.04a-10 bc -3*10 b
                                             7 2
                         c'=              3*10 b

     with initial conditions a=1.0, b=c=0.0 at x=0.0. We solve each of
     the following problems with local error tolerances 1.0E-3 and 1.0
     E-4.

     (i)   To integrate to x=10.0 producing output at intervals of 2.0
           until a point is encountered where a=0.9. The Jacobian is
           calculated numerically.

     (ii)  As (i) but with the Jacobian calculated analytically.

     (iii) As (i) but with no intermediate output.

     (iv)  As (i) but with no termination on a root-finding condition.

     (v)   Integrating the equations as in (i) but with no
           intermediate output and no root-finding termination
           condition.

     The example program is not reproduced here. The source code for
     all example programs is distributed with the NAG Foundation
     Library software and should be available on-line.

D02 -- Ordinary Differential Equations D02GAF
D02GAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D02GAF solves the two-point boundary-value problem with assigned boundary values for a system of ordinary differential equations, using a deferred correction technique and a Newton iteration.

2. Specification

```
       SUBROUTINE D02GAF (U, V, N, A, B, TOL, FCN, MNP, X, Y, NP,
      1                   W, LW, IW, LIW, IFAIL)
       INTEGER          N, MNP, NP, LW, IW(LIW), LIW, IFAIL
       DOUBLE PRECISION U(N,2), V(N,2), A, B, TOL, X(MNP), Y
      1                 (N,MNP), W(LW)
       EXTERNAL         FCN
```

3. Description

D02GAF solves a two-point boundary-value problem for a system of n differential equations in the interval [a,b]. The system is written in the form

$$y'_i = f_i(x, y_1, y_2, \ldots, y_n) , \quad i=1,2,\ldots,n \qquad (1)$$

and the derivatives are evaluated by a subroutine FCN supplied by the user. Initially, n boundary values of the variables y_i must be specified (assigned), some at a and some at b. The user also supplies estimates of the remaining n boundary values and all the boundary values are used in constructing an initial approximation to the solution. This approximate solution is corrected by a finite-difference technique with deferred correction allied with a Newton iteration to solve the finite-difference equations. The technique used is described fully in Pereyra [1]. The Newton iteration requires a Jacobian matrix $\frac{ddf_i}{ddy_j}$ and this is calculated by numerical differentiation using an algorithm described in Curtis et al [2].

The user supplies an absolute error tolerance and may also supply an initial mesh for the construction of the finite-difference equations (alternatively a default mesh is used). The algorithm constructs a solution on a mesh defined by adding points to the initial mesh. This solution is chosen so that the error is everywhere less than the user's tolerance and so that the error is approximately equidistributed on the final mesh. The solution is returned on this final mesh.

If the solution is required at a few specific points then these should be included in the initial mesh. If on the other hand the solution is required at several specific points then the user should use the interpolation routines provided in Chapter E01 if these points do not themselves form a convenient mesh.

5. Parameters

1: U(N,2) -- DOUBLE PRECISION array Input
On entry: U(i,1) must be set to the known (assigned) or estimated values of y_i at a and U(i,2) must be set to the known or estimated values of y_i at b, for i=1,2,...,n.

2: V(N,2) -- DOUBLE PRECISION array Input
On entry: V(i,j) must be set to 0.0 if U(i,j) is a known (assigned) value and to 1.0 if U(i,j) is an estimated value, i=1,2,...,n; j=1,2. Constraint: precisely N of the V(i,j) must be set to 0.0, i.e., precisely N of the U(i,j) must be known values, and these must not be all at a or all at b.

3: N -- INTEGER Input
On entry: the number of equations. Constraint: N >= 2.

4: A -- DOUBLE PRECISION Input
On entry: the left-hand boundary point, a.

5: B -- DOUBLE PRECISION Input
On entry: the right-hand boundary point, b. Constraint: B > A.

6: TOL -- DOUBLE PRECISION Input
On entry: a positive absolute error tolerance. If

$$a=x_1<x_2<...<x_{NP}=b$$

is the final mesh, $z_j(x_i)$ is the jth component of the approximate solution at x_i, and $y_j(x)$ is the jth component of the true solution of equation (1) (see Section 3) and the boundary conditions, then, except in extreme cases, it is expected that

$$|z_j(x_i)-y_j(x_i)|<=TOL\ ,\ i=1,2,...,NP;j=1,2,...,n \qquad (2)$$

Constraint: TOL > 0.0.

7: FCN -- SUBROUTINE, supplied by the user.
External Procedure
FCN must evaluate the functions f_i (i.e., the derivatives y'_i) at the general point x.

Its specification is:

```
       SUBROUTINE FCN (X, Y, F)
       DOUBLE PRECISION X, Y(n), F(n)
```

where n is the actual value of N in the call of D02GAF.

1: X -- DOUBLE PRECISION Input
On entry: the value of the argument x.

2: Y(*) -- DOUBLE PRECISION array Input
On entry: the value of the argument y_i, for $i=1,2,...,n$.

3: F(*) -- DOUBLE PRECISION array Output
On exit: the values of f_i, for $i=1,2,...,n$.

FCN must be declared as EXTERNAL in the (sub)program from which D02GAF is called. Parameters denoted as Input must not be changed by this procedure.

```
 8:  MNP -- INTEGER                                        Input
     On entry: the maximum permitted number of mesh points.
     Constraint: MNP >= 32.

 9:  X(MNP) -- DOUBLE PRECISION array               Input/Output
     On entry: if NP >= 4 (see NP below), the first NP elements
     must define an initial mesh. Otherwise the elements of X
     need not be set. Constraint:
                A=X(1)<X(2)<...<X(NP)=B for NP>=4            (3)
     On exit: X(1),X(2),...,X(NP) define the final mesh (with
     the returned value of NP) satisfying the relation (3).

10:  Y(N,MNP) -- DOUBLE PRECISION array                   Output
     On exit: the approximate solution z (x ) satisfying (2), on
                                        j  i
     the final mesh, that is
             Y(j,i)=z (x ) , i=1,2,...,NP;j=1,2,...,n,
                     j  i
     where NP is the number of points in the final mesh.

     The remaining columns of Y are not used.

11:  NP -- INTEGER                                  Input/Output
     On entry: determines whether a default or user-supplied
     mesh is used. If NP = 0, a default value of 4 for NP and a
     corresponding equispaced mesh X(1),X(2),...,X(NP) are used.
     If NP >= 4, then the user must define an initial mesh using
     the array X as described. Constraint: NP = 0 or 4 <= NP <=
     MNP. On exit: the number of points in the final (returned)
     mesh.

12:  W(LW) -- DOUBLE PRECISION array                   Workspace

13:  LW -- INTEGER                                         Input
     On entry: the length of the array W as declared in the
                                                 2        2
     calling (sub)program. Constraint: LW>=MNP*(3N +6N+2)+4N +4N

14:  IW(LIW) -- INTEGER array                          Workspace

15:  LIW -- INTEGER                                        Input
     On entry: the length of the array IW as declared in the
                                                       2
     calling (sub)program. Constraint: LIW>=MNP*(2N+1)+N +4N+2.

16:  IFAIL -- INTEGER                               Input/Output
     For this routine, the normal use of IFAIL is extended to
     control the printing of error and warning messages as well
     as specifying hard or soft failure (see the Essential
     Introduction).
     Before entry, IFAIL must be set to a value with the decimal
     expansion cba, where each of the decimal digits c, b and a
     must have a value of 0 or 1.
     a=0   specifies hard failure, otherwise soft failure;

     b=0   suppresses error messages, otherwise error messages
           will be printed (see Section 6);

     c=0   suppresses warning messages, otherwise warning
           messages will be printed (see Section 6).
     The recommended value for inexperienced users is 110 (i.e.,
     hard failure with all messages printed).

     Unless the routine detects an error (see Section 6), IFAIL
     contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     One or more of the parameters N, TOL, NP, MNP, LW or LIW has
     been incorrectly set, or B <= A, or the condition (3) on X
     is not satisfied, or the number of known boundary values
     (specified by V) is not N.

IFAIL= 2
     The Newton iteration has failed to converge. This could be
     due to there being too few points in the initial mesh or to
     the initial approximate solution being too inaccurate. If
     this latter reason is suspected the user should use
     subroutine D02RAF instead. If the warning 'Jacobian matrix
     is singular' is printed this could be due to specifying zero
     estimated boundary values and these should be varied. This
     warning could also be printed in the unlikely event of the
     Jacobian matrix being calculated inaccurately. If the user
     cannot make changes to prevent the warning then subroutine
     D02RAF should be used.

IFAIL= 3
     The Newton iteration has reached round-off level. It could
     be, however, that the answer returned is satisfactory. This
     error might occur if too much accuracy is requested.

IFAIL= 4
     A finer mesh is required for the accuracy requested; that is
     MNP is not large enough.

IFAIL= 5
     A serious error has occurred in a call to D02GAF. Check all
     array subscripts and subroutine parameter lists in calls to
     D02GAF. Seek expert help.
```

7. Accuracy

The solution returned by the routine will be accurate to the user's tolerance as defined by the relation (2) except in extreme circumstances. If too many points are specified in the initial mesh, the solution may be more accurate than requested and the error may not be approximately equidistributed.

8. Further Comments

The time taken by the routine depends on the difficulty of the problem, the number of mesh points used (and the number of different meshes used), the number of Newton iterations and the number of deferred corrections.

The user is strongly recommended to set IFAIL to obtain self-explanatory error messages, and also monitoring information about the course of the computation. The user may select the channel numbers on which this output is to appear by calls of X04AAF (for error messages) or X04ABF (for monitoring information) - see Section 9 for an example. Otherwise the default channel numbers will be used, as specified in the implementation document.

A common cause of convergence problems in the Newton iteration is the user specifying too few points in the initial mesh. Although the routine adds points to the mesh to improve accuracy it is unable to do so until the solution on the initial mesh has been calculated in the Newton iteration.

If the user specifies zero known and estimated boundary values, the routine constructs a zero initial approximation and in many cases the Jacobian is singular when evaluated for this approximation, leading to the breakdown of the Newton iteration.

The user may be unable to provide a sufficiently good choice of initial mesh and estimated boundary values, and hence the Newton iteration may never converge. In this case the continuation facility provided in D02RAF is recommended.

In the case where the user wishes to solve a sequence of similar problems, the final mesh from solving one case is strongly recommended as the initial mesh for the next.

```
          9. Example

          We solve the differential equation

                                                    2
                              y'''=-yy''-(beta)(1-y' )

          with boundary conditions

                                 y(0)=y'(0)=0,

                                   y'(10)=1

          for (beta)=0.0 and (beta)=0.2 to an accuracy specified by TOL=1.0
          E-3. We solve first the simpler problem with (beta)=0.0 using an
          equispaced mesh of 26 points and then we solve the problem with
          (beta)=0.2 using the final mesh from the first problem.

          Note the call to X04ABF prior to the call to D02GAF.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D02GBF solves a general linear two-point boundary value problem for a system of ordinary differential equations using a deferred correction technique.

2. Specification

```
       SUBROUTINE D02GBF (A, B, N, TOL, FCNF, FCNG, C, D, GAM,
      1                   MNP, X, Y, NP, W, LW, IW, LIW, IFAIL)
       INTEGER          N, MNP, NP, LW, IW(LIW), LIW, IFAIL
       DOUBLE PRECISION A, B, TOL, C(N,N), D(N,N), GAM(N), X(MNP),
      1                 Y(N,MNP), W(LW)
       EXTERNAL         FCNF, FCNG
```

3. Description

D02GBF solves the linear two-point boundary value problem for a system of n ordinary differential equations in the interval

[a,b]. The system is written in the form

$$y'=F(x)y+g(x) \qquad (1)$$

and the boundary conditions are written in the form

$$Cy(a)+Dy(b)=(gamma) \qquad (2)$$

Here F(x), C and D are n by n matrices, and g(x) and (gamma) are n-component vectors. The approximate solution to (1) and (2) is found using a finite-difference method with deferred correction. The algorithm is a specialisation of that used in subroutine D02RAF which solves a nonlinear version of (1) and (2). The nonlinear version of the algorithm is described fully in Pereyra [1].

The user supplies an absolute error tolerance and may also supply an initial mesh for the construction of the finite-difference equations (alternatively a default mesh is used). The algorithm constructs a solution on a mesh defined by adding points to the initial mesh. This solution is chosen so that the error is everywhere less than the user's tolerance and so that the error is approximately equidistributed on the final mesh. The solution is returned on this final mesh.

If the solution is required at a few specific points then these should be included in the initial mesh. If, on the other hand, the solution is required at several specific points, then the user should use the interpolation routines provided in Chapter E01 if these points do not themselves form a convenient mesh.

Lecture Notes in Computer Science. (ed B Childs, M Scott, J W Daniel, E Denman and P Nelson) 76 Springer-Verlag.

5. Parameters

1: A -- DOUBLE PRECISION Input
On entry: the left-hand boundary point, a.

2: B -- DOUBLE PRECISION Input
On entry: the right-hand boundary point, b. Constraint: B > A.

3: N -- INTEGER Input
On entry: the number of equations; that is n is the order of system (1). Constraint: N >= 2.

4: TOL -- DOUBLE PRECISION Input
On entry: a positive absolute error tolerance. If

$$a=x_1<x_2<...<x_{NP}=b$$

is the final mesh, z(x) is the approximate solution from D02GBF and y(x) is the true solution of equations (1) and (2) then, except in extreme cases, it is expected that

$$||z-y||<=TOL \qquad (3)$$

where

$$||u||=\max_{1<=i<=N} \max_{1<=j<=NP} |u_i(x_j)|.$$

Constraint: TOL > 0.0.

5: FCNF -- SUBROUTINE, supplied by the user.
External Procedure
FCNF must evaluate the matrix F(x) in (1) at a general point x.

Its specification is:

```
      SUBROUTINE FCN (X, F)
      DOUBLE PRECISION X, F(n,n)
```

```
where n is the actual value of N in the call of D02GBF.

 1:  X -- DOUBLE PRECISION                             Input
     On entry: the value of the independent variable x.

 2:  F(n,n) -- DOUBLE PRECISION array                 Output
     On exit: the (i,j)th element of the matrix F(x), for
     i,j=1,2,...,n. (See Section 9 for an example.)
FCN must be declared as EXTERNAL in the (sub)program
from which D02GBF is called. Parameters denoted as
Input must not be changed by this procedure.

6:  FCNG -- SUBROUTINE, supplied by the user.
                                          External Procedure
FCNG must evaluate the vector g(x) in (1) at a general point
x.

Its specification is:

       SUBROUTINE FCNG (X, G)
       DOUBLE PRECISION X, G(n)
where n is the actual value of N in the call of D02GBF.

 1:  X -- DOUBLE PRECISION                             Input
     On entry: the value of the independent variable x.

 2:  G(*) -- DOUBLE PRECISION array                   Output
     On exit: the ith element of the vector g(x), for
     i=1,2,...,n. (See Section Section 9 for an example.)
FCNG must be declared as EXTERNAL in the (sub)program
from which D02GBF is called. Parameters denoted as
Input must not be changed by this procedure.

7:  C(N,N) -- DOUBLE PRECISION array            Input/Output

8:  D(N,N) -- DOUBLE PRECISION array            Input/Output

9:  GAM(N) -- DOUBLE PRECISION array            Input/Output
On entry: the arrays C and D must be set to the matrices C
and D in (2). GAM must be set to the vector (gamma) in (2).
On exit: the rows of C and D and the components of GAM are
re-ordered so that the boundary conditions are in the order:
  (i)   conditions on y(a) only;

  (ii)  condition involving y(a) and y(b); and

  (iii) conditions on y(b) only.

The routine will be slightly more efficient if the arrays C,
D and GAM are ordered in this way before entry, and in this
```

```
     event they will be unchanged on exit.

     Note that the problems (1) and (2) must be of boundary value
     type, that is neither C nor D may be identically zero. Note
     also that the rank of the matrix [C,D] must be n for the
     problem to be properly posed. Any violation of these
     conditions will lead to an error exit.

 10: MNP -- INTEGER                                        Input
     On entry: the maximum permitted number of mesh points.
     Constraint: MNP >= 32.

 11: X(MNP) -- DOUBLE PRECISION array               Input/Output
     On entry: if NP >= 4 (see NP below), the first NP elements
     must define an initial mesh. Otherwise the elements of x
     need not be set. Constraint:
               A=X(1)<X(2)<...<X(NP)=B, for NP>=4.           (4)
     On exit: X(1),X(2),...,X(NP) define the final mesh (with the
     returned value of NP) satisfying the relation (4).

 12: Y(N,MNP) -- DOUBLE PRECISION array                   Output
     On exit: the approximate solution z(x) satisfying (3), on
     the final mesh, that is
               Y(j,i)=z (x ) , i=1,2,...,NP;j=1,2,...,n
                       j  i
     where NP is the number of points in the final mesh.

     The remaining columns of Y are not used.

 13: NP -- INTEGER                                  Input/Output
     On entry: determines whether a default mesh or user-supplied
     mesh is used. If NP = 0, a default value of 4 for NP and a
     corresponding equispaced mesh X(1),X(2),...,X(NP) are used.
     If NP >= 4, then the user must define an initial mesh X as
     in (4) above. On exit: the number of points in the final
     (returned) mesh.

 14: W(LW) -- DOUBLE PRECISION array                   Workspace

 15: LW -- INTEGER                                         Input
     On entry: the length of the array W, Constraint:
              2         2
     LW>=MNP*(3N +5N+2)+3N +5N.

 16: IW(LIW) -- INTEGER array                          Workspace

 17: LIW -- INTEGER                                        Input
     On entry: the length of the array IW. Constraint:
     LIW>=MNP*(2N+1)+N.
```

```
18:  IFAIL -- INTEGER                                Input/Output
     For this routine, the normal use of IFAIL is extended to
     control the printing of error and warning messages as well
     as specifying hard or soft failure (see the Essential
     Introduction).

     Before entry, IFAIL must be set to a value with the decimal
     expansion cba, where each of the decimal digits c, b and a
     must have a value of 0 or 1.
     a=0   specifies hard failure, otherwise soft failure;

     b=0   suppresses error messages, otherwise error messages
           will be printed (see Section 6);

     c=0   suppresses warning messages, otherwise warning
           messages will be printed (see Section 6).
     The recommended value for inexperienced users is 110 (i.e.,
     hard failure with all messages printed).

     Unless the routine detects an error (see Section 6), IFAIL
     contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

For each error, an explanatory error message is output on the
current error message unit (as defined by X04AAF), unless
suppressed by the value of IFAIL on entry.

IFAIL= 1
     One or more of the parameters N, TOL, NP, MNP, LW or LIW is
     incorrectly set, B <= A or the condition (4) on X is not
     satisfied.

IFAIL= 2
     There are three possible reasons for this error exit to be
     taken:
       (i)  one of the matrices C or D is identically zero (that
            is the problem is of initial value and not boundary
            value type). In this case, IW(1) = 0 on exit;

       (ii) a row of C and the corresponding row of D are
            identically zero (that is the boundary conditions are
            rank deficient). In this case, on exit IW(1) contains
            the index of the first such row encountered; and

       (iii more than n of the columns of the n by 2n matrix [C,D
       )    ] are identically zero (that is the boundary
            conditions are rank deficient). In this case, on exit
```

```
              IW(1) contains minus the number of non-identically
              zero columns.

    IFAIL= 3
         The routine has failed to find a solution to the specified
         accuracy. There are a variety of possible reasons including:
           (i)   the boundary conditions are rank deficient, which may
                 be indicated by the message that the Jacobian is
                 singular. However this is an unlikely explanation for
                 the error exit as all rank deficient boundary
                 conditions should lead instead to error exits with
                 either IFAIL = 2 or IFAIL = 5; see also (iv) below;

           (ii)  not enough mesh points are permitted in order to
                 attain the required accuracy. This is indicated by NP
                 = MNP on return from a call to D02GBF. This
                 difficulty may be aggravated by a poor initial choice
                 of mesh points;

           (iii) the accuracy requested cannot be attained on the
                 computer being used; and

           (iv)  an unlikely combination of values of F(x) has led to
                 a singular Jacobian. The error should not persist if
                 more mesh points are allowed.

    IFAIL= 4
         A serious error has occurred in a call to D02GBF. Check all
         array subscripts and subroutine parameter lists in calls to
         D02GBF. Seek expert help.

    IFAIL= 5
         There are two possible reasons for this error exit which
         occurs when checking the rank of the boundary conditions by
         reduction to a row echelon form:
              (i) at least one row of the n by 2n matrix [C,D] is a
              linear combination of the other rows and hence the
              boundary conditions are rank deficient. The index of
              the first such row encountered is given by IW(1) on
              exit; and

              (ii) as (i) but the rank deficiency implied by this
              error exit has only been determined up to a numerical
              tolerance. Minus the index of the first such row
              encountered is given by IW(1) on exit.
         In case (ii) above there is some doubt as to the rank
         deficiency of the boundary conditions. However even if the
         boundary conditions are not rank deficient they are not
         posed in a suitable form for use with this routine.
```

For example, if

```
                                                  ((gamma) )
         (1 0        )     (1 0)          (       1)
      C=(1 (epsilon)) , D=(1 0) , (gamma)=((gamma) )
                                                  (       2)
```

and (epsilon) is small enough, this error exit is likely to be taken. A better form for the boundary conditions in this case would be

```
                               ((gamma)                   )
                               (       1                  )
  (1 0)     (1 0)              (         -1               )
C=(0 1) , D=(0 0) , (gamma)=((epsilon)  ((gamma) -(gamma) ))
                               (                   2       1 )
```

7. Accuracy

The solution returned by the routine will be accurate to the user's tolerance as defined by the relation (3) except in extreme circumstances. If too many points are specified in the initial mesh, the solution may be more accurate than requested and the error may not be approximately equidistributed.

8. Further Comments

The time taken by the routine depends on the difficulty of the problem, the number of mesh points (and meshes) used and the number of deferred corrections.

The user is strongly recommended to set IFAIL to obtain self-explanatory error messages, and also monitoring information about the course of the computation. The user may select the channel numbers on which this output is to appear by calls of X04AAF (for error messages) or X04ABF (for monitoring information) - see Section 9 for an example. Otherwise the default channel numbers will be used, as specified in the implementation document.

In the case where the user wishes to solve a sequence of similar problems, the use of the final mesh from one case is strongly recommended as the initial mesh for the next.

9. Example

We solve the problem (written as a first order system)

```
                        (epsilon)y''+y'=0
```

with boundary conditions

```
                         y(0)=0,  y(1)=1
```

```
                                   -1                 -2
         for the cases (epsilon)=10   and (epsilon)=10   using the default
         initial mesh in the first case, and the final mesh of the first
         case as initial mesh for the second (more difficult) case. We
         give the solution and the error at each mesh point to illustrate
         the accuracy of the method given the accuracy request TOL=1.0E-3.

         Note the call to X04ABF prior to the call to D02GBF.

         The example program is not reproduced here. The source code for
         all example programs is distributed with the NAG Foundation
         Library software and should be available on-line.

\begin{verbatim}

D02KEF(3NAG)                D02KEF                 D02KEF(3NAG)

     D02 -- Ordinary Differential Equations                    D02KEF
             D02KEF -- NAG Foundation Library Routine Document

     Note: Before using this routine, please read the Users' Note for
     your implementation to check implementation-dependent details.
     The symbol (*) after a NAG routine name denotes a routine that is
     not included in the Foundation Library.

     1. Purpose

     D02KEF finds a specified eigenvalue of a regular singular second-
     order Sturm-Liouville system on a finite or infinite range, using
     a Pruefer transformation and a shooting method. It also reports
     values of the eigenfunction and its derivatives. Provision is
```

made for discontinuities in the coefficient functions or their
derivatives.

2. Specification

```
       SUBROUTINE D02KEF (XPOINT, M, MATCH, COEFFN, BDYVAL, K,
      1                   TOL, ELAM, DELAM, HMAX, MAXIT, MAXFUN,
      2                   MONIT, REPORT, IFAIL)
       INTEGER          M, MATCH, K, MAXIT, MAXFUN, IFAIL
       DOUBLE PRECISION XPOINT(M), TOL, ELAM, DELAM, HMAX(2,M)
       EXTERNAL         COEFFN, BDYVAL, MONIT, REPORT
```

3. Description

D02KEF has essentially the same purpose as D02KDF(*) with minor
modifications to enable values of the eigenfunction to be
obtained after convergence to the eigenvalue has been achieved.

```
                                           ~~~~~~~~
It first finds a specified eigenvalue (lambda) of a Sturm-
```
Liouville system defined by a self-adjoint differential equation
of the second-order

```
                (p(x)y')'+q(x;(lambda))y=0, a<x<b
```

together with the appropriate boundary conditions at the two
(finite or infinite) end-points a and b. The functions p and q,
which are real-valued, must be defined by a subroutine COEFFN.
The boundary conditions must be defined by a subroutine BDYVAL,
and, in the case of a singularity at a or b, take the form of an
asymptotic formula for the solution near the relevant end-point.

```
                                      ~~~~~~~~
When the final estimate (lambda)=(lambda) of the eigenvalue has
```
been found, the routine integrates the differential equation once
more with that value of (lambda), and with initial conditions
chosen so that the integral

```
                  b
                  /    2    ddq
               S= |y(x)  ----------(x;(lambda))dx
                  /      dd(lambda)
                  a
```

is approximately one. When q(x;(lambda)) is of the form
(lambda)w(x)+q(x), which is the most common case, S represents
the square of the norm of y induced by the inner product

```
                           b
                           /
```

```
                     <f,g>= |f(x)g(x)w(x)dx,
                            /
                            a
```

with respect to which the eigenfunctions are mutually orthogonal.
This normalisation of y is only approximate, but experience shows
that S generally differs from unity by only one or two per cent.

During this final integration the REPORT routine supplied by the
user is called at each integration mesh point x. Sufficient
information is returned to permit the user to compute y(x) and
y'(x) for printing or plotting. For reasons described in Section
8.2, D02KEF passes across to REPORT, not y and y', but the Pru
efer variables (beta), (phi) and (rho) on which the numerical
method is based. Their relationship to y and y' is given by the
equations

```
         ______   ( (rho))   ( (phi))
p(x)y'=\/(beta)exp( -----)cos( -----);
                  (   2  )   (   2  )

           1       ( (rho))   ( (phi))
     y= --------exp( -----)sin( -----).
          ______   (   2  )   (   2  )
        \/(beta)
```

For the theoretical basis of the numerical method to be valid,
the following conditions should hold on the coefficient
functions:

(a) p(x) must be non-zero and of one sign throughout the
interval (a,b); and,

```
          ddq
(b)    ---------- must be of one sign throughout (a,b) for all
       dd(lambda)
      relevant values of (lambda), and must not be identically
      zero as x varies, for any (lambda).
```

Points of discontinuity in the functions p and q or their
derivatives are allowed, and should be included as 'break-points'
in the array XPOINT.

A good account of the theory of Sturm-Liouville systems, with
some description of Pruefer transformations, is given in Birkhoff
and Rota [4], Chapter X. An introduction for the user of Pruefer
transformations for the numerical solution of eigenvalue problems
arising from physics and chemistry is Bailey [2].

The scaled Pruefer method is fairly recent, and is described in a short note by Pryce [6] and in some detail in the technical report [5].

5. Parameters

1: XPOINT(M) -- DOUBLE PRECISION array Input
On entry: the points where the boundary conditions computed by BDYVAL are to be imposed, and also any break-points, i.e., XPOINT(1) to XPOINT(m) must contain values $x_1,...,x_m$ such that

$$x_1 <= x_2 < x_3 < ... < x_{m-1} <= x_m$$

with the following meanings:

(a) x_1 and x_m are the left and right end-points, a and b, of the domain of definition of the Sturm-Liouville system if these are finite. If either a or b is infinite, the corresponding value x_1 or x_m may be a more-or-less arbitrarily 'large' number of appropriate sign.

(b) x_2 and x_{m-1} are the Boundary Matching Points (BMP's), that is the points at which the left and right boundary conditions computed in BDYVAL are imposed.

If the left-hand end-point is a regular point then the user should set $x_2=x_1$ (=a), while if it is a singular point the user must set $x_2>x_1$. Similarly $x_{m-1}=x_m$ (=b) if the right-hand end-point is regular, and $x_{m-1}<x_m$ if it is singular.

(c) The remaining m-4 points $x_3,...,x_{m-2}$, if any, define 'break-points' which divide the interval $[x_2,x_{m-1}]$ into m-3 sub-intervals

$$i_1=[x_2,x_3],...,i_{m-3}=[x_{m-2},x_{m-1}]$$

Numerical integration of the differential equation is stopped and restarted at each break-point. In simple cases no break-points are needed. However if p(x) or q(x;(lambda)) are given by different formulae in different parts of the range, then integration is more efficient if the range is broken up by break-points in the appropriate way. Similarly points where any jumps occur in p(x) or q(x;(lambda)), or in their derivatives up to the fifth order, should appear as break-points.

Constraint: X(1) <= X(2) < ... < X(M-1) <= X(M).

2: M -- INTEGER Input
On entry: the number of points in the array XPOINT.
Constraint: M >= 4.

3: MATCH -- INTEGER Input/Output
On entry: MATCH must be set to the index of the 'break-point ' to be used as the matching point (see Section 8.3). If MATCH is set to a value outside the range [2,m-1] then a default value is taken, corresponding to the break-point nearest the centre of the interval [XPOINT(2),XPOINT(m-1)].
On exit: the index of the break-point actually used as the matching point.

4: COEFFN -- SUBROUTINE, supplied by the user.
External Procedure
COEFFN must compute the values of the coefficient functions p(x) and q(x;(lambda)) for given values of x and (lambda). Section 3 states conditions which p and q must satisfy.

Its specification is:

```
       SUBROUTINE COEFFN (P, Q, DQDL, X, ELAM, JINT)
       DOUBLE PRECISION P, Q, DQDL, X, ELAM
       INTEGER          JINT

  1:  P -- DOUBLE PRECISION                            Output
      On exit: the value of p(x) for the current value of x.

  2:  Q -- DOUBLE PRECISION                            Output
      On exit: the value of q(x;(lambda)) for the current
      value of x and the current trial value of (lambda).

  3:  DQDL -- DOUBLE PRECISION                         Output
                                 ddq
      On exit: the value of  ----------(x;(lambda)) for the
                             dd(lambda)
      current value of x and the current trial value of
      (lambda). However DQDL is only used in error estimation
      and an approximation (say to within 20%) will suffice.

  4:  X -- DOUBLE PRECISION                            Input
      On entry: the current value of x.

  5:  ELAM -- DOUBLE PRECISION                         Input
      On entry: the current trial value of the eigenvalue
      parameter (lambda).

  6:  JINT -- INTEGER                                  Input
      On entry: the index j of the sub-interval i  (see
                                                 j
      specification of XPOINT) in which x lies.
 See Section 8.4 and Section 9 for examples.

 COEFFN must be declared as EXTERNAL in the (sub)program
 from which D02KEF is called. Parameters denoted as
 Input must not be changed by this procedure.

5:  BDYVAL -- SUBROUTINE, supplied by the user.
                                        External Procedure
 BDYVAL must define the boundary conditions. For each end-
 point, BDYVAL must return (in YL or YR) values of y(x) and
 p(x)y'(x) which are consistent with the boundary conditions
 at the end-points; only the ratio of the values matters.
 Here x is a given point (XL or XR) equal to, or close to,
 the end-point.

 For a regular end-point (a, say), x=a; and a boundary
 condition of the form
                     c y(a)+c y'(a)=0
                      1      2
```

can be handled by returning constant values in YL, e.g. YL(1)=c_2 and YL(2)=$-c_1$ p(a).

For a singular end-point however, YL(1) and YL(2) will in general be functions of XL and ELAM, and YR(1) and YR(2) functions of XR and ELAM, usually derived analytically from a power-series or asymptotic expansion. Examples are given in Section 8.5 Section 9.

Its specification is:

```
      SUBROUTINE BDYVAL (XL, XR, ELAM, YL, YR))
      DOUBLE PRECISION XL, XR, ELAM, YL(3), YR(3)
```

1: XL -- DOUBLE PRECISION Input
On entry: if a is a regular end-point of the system (so that $a=x_1=x_2$), then XL contains a. If a is a singular point (so that $a<=x_1<x_2$), then XL contains a point x such that $x_1<x<=x_2$).

2: XR -- DOUBLE PRECISION Input
On entry: if b is a regular end-point of the system (so that $x_{m-1}=x_m=b$), then XR contains b. If b is a singular point (so that $x_{m-1}<x_m<=b$), then XR contains a point x such that $x_{m-1}<=x<x_m$.

3: ELAM -- DOUBLE PRECISION Input
On entry: the current trial value of (lambda).

4: YL(3) -- DOUBLE PRECISION array Output
On exit: YL(1) and YL(2) should contain values of y(x) and p(x)y'(x) respectively (not both zero) which are consistent with the boundary condition at the left-hand end-point, given by x = XL. YL(3) should not be set.

5: YR(3) -- DOUBLE PRECISION array Output
On exit: YR(1) and YR(2) should contain values of y(x) and p(x)y'(x) respectively (not both zero) which are consistent with the boundary condition at the right-hand end-point, given by x = XR. YR(3) should not be set.

BDYVAL must be declared as EXTERNAL in the (sub)program

```
     from which D02KEF is called. Parameters denoted as
     Input must not be changed by this procedure.

 6:  K -- INTEGER                                        Input
     On entry: the index k of the required eigenvalue when the
     eigenvalues are ordered
     (lambda) <(lambda) <(lambda) <...<(lambda) <....
             0        1        2            k
     Constraint: K >= 0.

 7:  TOL -- DOUBLE PRECISION                             Input
     On entry: the tolerance parameter which determines the
     accuracy of the computed eigenvalue. The error estimate held
     in DELAM on exit satisfies the mixed absolute/relative error
     test
                   DELAM<=TOL*max(1.0,|ELAM|)                (*)
     where ELAM is the final estimate of the eigenvalue. DELAM is
     usually somewhat smaller than the right-hand side of (*) but
     not several orders of magnitude smaller. Constraint: TOL >
     0.0.

 8:  ELAM -- DOUBLE PRECISION                     Input/Output
                                                  ~~~~~~~~
     On entry: an initial estimate of the eigenvalue (lambda).
     On exit: the final computed estimate, whether or not an
     error occurred.

 9:  DELAM -- DOUBLE PRECISION                    Input/Output
     On entry: an indication of the scale of the problem in the
     (lambda)-direction. DELAM holds the initial 'search step'
     (positive or negative). Its value is not critical but the
     first two trial evaluations are made at ELAM and ELAM +
     DELAM, so the routine will work most efficiently if the
     eigenvalue lies between these values. A reasonable choice
     (if a closer bound is not known) is half the distance
     between adjacent eigenvalues in the neighbourhood of the one
     sought. In practice, there will often be a problem, similar
     to the one in hand but with known eigenvalues, which will
     help one to choose initial values for ELAM and DELAM.

     If DELAM = 0.0 on entry, it is given the default value of
     0.25*max(1.0,|ELAM|). On exit: with IFAIL = 0, DELAM holds
     an estimate of the absolute error in the computed
                                 ~~~~~~~~
     eigenvalue, that is |(lambda)-ELAM|~=DELAM. (In Section 8.2
     we discuss the assumptions under which this is true.) The
     true error is rarely more than twice, or less than a tenth,
     of the estimated error.

     With IFAIL /= 0, DELAM may hold an estimate of the error, or
```

```
     its initial value, depending on the value of IFAIL. See
     Section 6 for further details.

 10: HMAX(2,M) -- DOUBLE PRECISION array             Input/Output
     On entry: HMAX(1,j) a maximum step size to be used by the
     differential equation code in the jth sub-interval i  (as
                                                         j
     described in the specification of parameter XPOINT), for
     j=1,2,...,m-3. If it is zero the routine generates a maximum
     step size internally.

     It is recommended that HMAX(1,j) be set to zero unless the
     coefficient functions p and q have features (such as a
     narrow peak) within the jth sub-interval that could be '
     missed' if a long step were taken. In such a case HMAX(1,j)
     should be set to about half the distance over which the
     feature should be observed. Too small a value will increase
     the computing time for the routine. See Section 8 for
     further suggestions.

     The rest of the array is used as workspace. On exit: HMAX(
     1,m-1) and HMAX(1,m) contain the sensitivity coefficients
     (sigma) ,(sigma) , described in Section 8.6. Other entries
            l        r
     contain diagnostic output in case of an error (see Section 6
     ).

 11: MAXIT -- INTEGER                                Input/Output
     On entry: a bound on n , the number of root-finding
                           r
     iterations allowed, that is the number of trial values of
     (lambda) that are used. If MAXIT <= 0, no such bound is
     assumed. (See also under MAXFUN.) Suggested value: MAXIT =
     0. On exit: MAXIT will have been decreased by the number of
     iterations actually performed, whether or not it was
     positive on entry.

 12: MAXFUN -- INTEGER                                      Input
     On entry: a bound on n , the number of calls to COEFFN made
                           f
     in any one root-finding iteration. If MAXFUN <= 0, no such
     bound is assumed. Suggested value: MAXFUN = 0.

     MAXFUN and MAXIT may be used to limit the computational cost
     of a call to D02KEF, which is roughly proportional to n *n .
                                                           r  f

 13: MONIT -- SUBROUTINE, supplied by the user.
                                          External Procedure
     MONIT is called by D02KEF at the end of each root-finding
```

```
iteration and allows the user to monitor the course of the
computation by printing out the parameters (see Section 8
for an example).
If no monitoring is required, the dummy subroutine D02KAY
may be used. (D02KAY is included in the NAG Foundation
Library).

Its specification is:

       SUBROUTINE MONIT (MAXIT, IFLAG, ELAM, FINFO)
       INTEGER          MAXIT, IFLAG
       DOUBLE PRECISION ELAM, FINFO(15)

 1:  MAXIT -- INTEGER                                  Input
     On entry: the current value of the parameter MAXIT of
     D02KEF; this is decreased by one at each iteration.

 2:  IFLAG -- INTEGER                                  Input
     On entry: IFLAG describes what phase the computation is
     in, as follows:
     IFLAG < 0
           an error occurred in the computation of the '
           miss-distance' at this iteration;

           an error exit from D02KEF with IFAIL =-IFLAG will
           follow.

     IFLAG = 1
           the routine is trying to bracket the eigenvalue
           ~~~~~~~~
           (lambda).

     IFLAG = 2
           the routine is converging to the eigenvalue
           ~~~~~~~~
           (lambda) (having already bracketed it).

 3:  ELAM -- DOUBLE PRECISION                          Input
     On entry: the current trial value of (lambda).

 4:  FINFO(15) -- DOUBLE PRECISION array               Input
     On entry: information about the behaviour of the
     shooting method, and diagnostic information in the case
     of errors. It should not normally be printed in full if
     no error has occurred (that is, if IFLAG > 0), though
     the first few components may be of interest to the
     user. In case of an error (IFLAG < 0) all the
     components of FINFO should be printed. The contents of
     FINFO are as follows:
```

```
FINFO(1): the current value of the 'miss-distance' or '
residual' function f((lambda)) on which the shooting
method is based. FINFO(1) is set to zero if IFLAG < 0.

FINFO(2): an estimate of the quantity dd(lambda)
defined as follows. Consider the perturbation in the
miss-distance f((lambda)) that would result if the
local error, in the solution of the differential
equation, were always positive and equal to its maximum
permitted value. Then dd(lambda) is the perturbation in
(lambda) that would have the same effect on f((lambda))
. Thus, at the zero of f((lambda)),|dd(lambda)| is an
approximate bound on the perturbation of the zero (that
is the eigenvalue) caused by errors in numerical
solution. If dd(lambda) is very large then it is
possible that there has been a programming error in
COEFFN such that q is independent of (lambda). If this
is the case, an error exit with IFAIL = 5 should
follow. FINFO(2) is set to zero if IFLAG < 0.

FINFO(3): the number of internal iterations, using the
same value of (lambda) and tighter accuracy tolerances,
needed to bring the accuracy (that is the value of
dd(lambda)) to an acceptable value. Its value should
normally be 1.0, and should almost never exceed 2.0.

FINFO(4): the number of calls to COEFFN at this
iteration.

FINFO(5): the number of successful steps taken by the
internal differential equation solver at this
iteration. A step is successful if it is used to
advance the integration (cf. COUT(8) in specification
of D02PAF(*)).

FINFO(6): the number of unsuccessful steps used by the
internal integrator at this iteration (cf. COUT(9) in
specification of D02PAF(*)).

FINFO(7): the number of successful steps at the maximum
step size taken by the internal integrator at this
iteration (cf. COUT(3) in specification of D02PAF(*)).

FINFO(8): is not used.

FINFO(9) to FINFO(15): set to zero, unless IFLAG < 0 in
which case they hold the following values describing
the point of failure:

FINFO(9): contains the index of the sub-interval where
```

```
          failure occurred, in the range 1 to m-3. In case of an
          error in BDYVAL, it is set to 0 or m-2 depending on
          whether the left or right boundary condition caused the
          error.

          FINFO(10): the value f the independent variable x, the
          point at which error occurred. In case of an error in
          BDYVAL, it is set to the value of XL or XR as
          appropriate (see the specification of BDYVAL).

          FINFO(11), FINFO(12), FINFO(13): the current values of
          the Pruefer dependent variables (beta), (phi) and (rho)
          respectively. These are set to zero in case of an error
          in BDYVAL.

          FINFO(14): the local-error tolerance being used by the
          internal integrator at the point of failure. This is
          set to zero in the case of an error in BDYVAL.

          FINFO(15): the last integration mesh point. This is set
          to zero in the case of an error in BDYVAL.
     MONIT must be declared as EXTERNAL in the (sub)program
     from which D02KEF is called. Parameters denoted as
     Input must not be changed by this procedure.

 14: REPORT -- SUBROUTINE, supplied by the user.
                                            External Procedure
     This routine provides the means by which the user may
     compute the eigenfunction y(x) and its derivative at each
     integration mesh point x. (See Section 8 for an example).

     Its specification is:

            SUBROUTINE REPORT (X, V, JINT)
            INTEGER         JINT
            DOUBLE PRECISION X, V(3)

      1:  X -- DOUBLE PRECISION                              Input
          On entry: the current value of the independent variable
          x. See Section 8.3 for the order in which values of x
          are supplied.

      2:  V(3) -- DOUBLE PRECISION array                     Input
          On entry: V(1), V(2), V(3) hold the current values of
          the Pruefer variables (beta), (phi), (rho)
          respectively.

      3:  JINT -- INTEGER                                    Input
          On entry: JINT indicates the sub-interval between
          break-points in which X lies exactly as for the routine
          COEFFN, except that at the extreme left end-point (when
          x = XPOINT(2)) JINT is set to 0 and at the extreme
          right end-point (when x=x =XPOINT(m-1)) JINT is set to
                                   r
          m-2.
     REPORT must be declared as EXTERNAL in the (sub)program
     from which D02KEF is called. Parameters denoted as
     Input must not be changed by this procedure.

15:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     A parameter error. All parameters (except IFAIL) are left
     unchanged. The reason for the error is shown by the value of
     HMAX(2,1) as follows:
     HMAX(2,1) = 1: M < 4;

     HMAX(2,1) = 2: K < 0;

     HMAX(2,1) = 3: TOL <= 0.0;

     HMAX(2,1) = 4: XPOINT(1) to XPOINT(m) are not in ascending
                    order.

                    HMAX(2,2) gives the position i in XPOINT
                    where this was detected.

IFAIL= 2
     At some call to BDYVAL, invalid values were returned, that
     is, either YL(1) = YL(2) = 0.0, or YR(1) = YR(2) = 0.0 (a
     programming error in BDYVAL). See the last call of MONIT for
     details.

     This error exit will also occur if p(x) is zero at the point
     where the boundary condition is imposed. Probably BDYVAL was
     called with XL equal to a singular end-point a or with XR
     equal to a singular end-point b.

IFAIL= 3
     At some point between XL and XR the value of p(x) computed
```

```
          by COEFFN became zero or changed sign. See the last call of
          MONIT for details.

     IFAIL= 4
          MAXIT > 0 on entry, and after MAXIT iterations the
          eigenvalue had not been found to the required accuracy.

     IFAIL= 5
          The 'bracketing' phase (with parameter IFLAG of MONIT equal
          to 1) failed to bracket the eigenvalue within ten
          iterations. This is caused by an error in formulating the
          problem (for example, q is independent of (lambda)), or by
          very poor initial estimates of ELAM, DELAM.

          On exit ELAM and ELAM + DELAM give the end-points of the
          interval within which no eigenvalue was located by the
          routine.

     IFAIL= 6
          MAXFUN > 0 on entry, and the last iteration was terminated
          because more than MAXFUN calls to COEFFN were used. See the
          last call of MONIT for details.

     IFAIL= 7
          To obtain the desired accuracy the local error tolerance was
          set so small at the start of some sub-interval that the
          differential equation solver could not choose an initial
          step size large enough to make significant progress. See the
          last call of MONIT for diagnostics.

     IFAIL= 8
          At some point inside a sub-interval the step size in the
          differenital equation solver was reduced to a value too
          small to make significant progress (for the same reasons as
          with IFAIL = 7). This could be due to pathological behaviour
          of p(x) and q(x;(lambda)) or to an unreasonable accuracy
          requirement or to the current value of (lambda) making the
          equations 'stiff'. See the last call of MONIT for details.

     IFAIL= 9
          TOL is too small for the problem being solved and the
          machine precision is being used. The final value of ELAM
          should be a very good approximation to the eigenvalue.

     IFAIL= 10
          C05AZF(*), called by D02KEF, has terminated with the error
          exit corresponding to a pole of the residual function
          f((lambda)). This error exit should not occur, but if it
          does, try solving the problem again with a smaller value for
          TOL.
```

IFAIL= 11
     A serious error has occurred in an internal call to D02KDY.
     Check all subroutine calls and array dimensions. Seek expert
     help.

IFAIL= 12
     A serious error has occurred in an internal call to
     C05AZF(*). Check all subroutine calls and array dimensions.
     Seek expert help.

     HMAX(2,1) holds the failure exit number from the routine
     where the failure occurred. In the case of a failure in
     C05AZF(*), HMAX(2,2) holds the value of parameter IND of
     C05AZF(*).

Note: error exits with IFAIL = 2, 3, 6, 7, 8, 11 are caused by being unable to set up or solve the differential equation at some iteration, and will be immediately preceded by a call of MONIT giving diagnostic information. For other errors, diagnostic information is contained in HMAX(2,j), for j=1,2,...,m, where appropriate.

7. Accuracy

See the discussion in Section 8.2.

8. Further Comments

8.1. Timing

The time taken by the routine depends on the complexity of the coefficient functions, whether they or their derivatives are rapidly changing, the tolerance demanded, and how many iterations are needed to obtain convergence. The amount of work per iteration is roughly doubled when TOL is divided by 16. To make the most economical use of the routine, one should try to obtain good initial values for ELAM and DELAM, and, where appropriate, good asymptotic formulae. The boundary matching points should not be set unnecessarily close to singular points. The extra time needed to compute the eigenfunction is principally the cost of one additional integration once the eigenvalue has been found.

8.2. General Description of the Algorithm

A shooting method, for differential equation problems containing unknown parameters, relies on the construction of a 'miss-distance function', which for given trial values of the parameters measures how far the conditions of the problem are from being met. The problem is then reduced to one of finding the

```
values of the parameters for which the miss-distance function is
zero, that is to a root-finding process. Shooting methods differ
mainly in how the miss-distance is defined.

This routine defines a miss-distance f((lambda)) based on the
rotation around the origin of the point P(x)=(p(x)y'(x),y(x)) in
the Phase Plane as the solution proceeds from a to b. The
boundary-conditions define the ray (i.e., two-sided line through
the origin) on which p(x) should start, and the ray on which it
should finish. The eigenvalue index k defines the total number of
half-turns it should make. Numerical solution is actually done by
matching point x=c. Then f((lambda)) is taken as the angle
between the rays to the two resulting points P (c) and P (c). A
                                             a        b
relative scaling of the py' and y axes, based on the behaviour of
the coefficient functions p and q, is used to improve the
numerical behaviour.

         Please see figure in printed Reference Manual

The resulting function f((lambda)) is monotonic over -
                                        ddq
infty<(lambda)<infty, increasing if  ---------->0 and decreasing
                                     dd(lambda)
     ddq
if  ----------<0, with a unique zero at the desired eigenvalue
    dd(lambda)
~~~~~~~~
(lambda). The routine measures f((lambda)) in units of a half-
turn. This means that as (lambda) increases, f((lambda)) varies
by about 1 as each eigenvalue is passed. (This feature implies
that the values of f((lambda)) at successive iterations -
especially in the early stages of the iterative process - can be
used with suitable extrapolation or interpolation to help the
choice of initial estimates for eigenvalues near to the one
currently being found.)

The routine actually computes a value for f((lambda)) with
errors, arising from the local errors of the differential
equation code and from the asymptotic formulae provided by the
user if singular points are involved. However, the error estimate
output in DELAM is usually fairly realistic, in that the actual
       ~~~~~~~~
error |(lambda)-ELAM| is within an order of magnitude of DELAM.

We pass the values of (beta), (phi), (rho) across through REPORT
rather than converting them to values of y, y' inside D02KEF, for
the following reasons. First, there may be cases where auxiliary
```

quantities can be more accurately computed from the Pruefer variables than from y and y'. Second, in singular problems on an infinite interval y and y' may underflow towards the end of the range, whereas the Pruefer variables remain well-behaved. Third, with high-order eigenvalues (and therefore highly oscillatory eigenfunctions) the eigenfunction may have a complete oscillation (or more than one oscillation) between two mesh points, so that values of y and y' at mesh points give a very poor representation of the curve. The probable behaviour of the Pruefer variables in this case is that (beta) and (rho) vary slowly whilst (phi) increases quickly: for all three Pruefer variables linear interpolation between the values at adjacent mesh points is probably sufficiently accurate to yield acceptable intermediate values of (beta), (phi), (rho) (and hence of y,y') for graphical purposes.

Similar considerations apply to the exponentially decaying 'tails Here (phi) has approximately constant value whilst (rho) increases rapidly in the direction of integration, though the step length is generally fairly small over such a range.

If the solution is output through REPORT at x-values which are too widely spaced, the step length can be controlled by choosing HMAX suitably, or, preferably, by reducing TOL. Both these choices will lead to more accurate eigenvalues and eigenfunctions but at some computational cost.

8.3. The Position of the Shooting Matching Point c

This point is always one of the values x_i in array XPOINT. It may be specified using the parameter MATCH. The default value is chosen to be the value of that x_i,2<=i<=m-1, that lies closest to the middle of the interval $[x_2,x_{m-1}]$. If there is a tie, the rightmost candidate is chosen. In particular if there are no break-points then $c=x_{m-1}$ $(=x_3)$ - that is the shooting is from left to right in this case. A break-point may be inserted purely to move c to an interior point of the interval, even though the form of the equations does not require it. This often speeds up convergence especially with singular problems.

Note that the shooting method used by the code integrates first from the left-hand end x_l, then from the right-hand end x_r, to meet at the matching point c in the middle. This will of course be reflected in printed or graphical output. The diagram shows a possible sequence of nine mesh points (tau) through (tau) in

```
                                              1            9
the order in which they appear, assuming there are just two sub-
intervals (so m=5).

                              Figure 1
         Please see figure in printed Reference Manual

Since the shooting method usually fails to match up the two 'legs
p(x)y' or both, at the matching point c. The code in fact 'shares
large jump does not imply an inaccurate eigenvalue, but implies
either

(a)    a badly chosen matching point: if q(x;(lambda)) has a '
       humped' shape, c should be chosen near the maximum value of
       q, especially if q is negative at the ends of the interval.

(b)    An inherently ill-conditioned problem, typically one where
       another eigenvalue is pathologically close to the one being
       sought. In this case it is extremely difficult to obtain an
       accurate eigenfunction.

In Section 9 below, we find the 11th eigenvalue and corresponding
eigenfunction of the equation

                                   2
             y''+((lambda)-x-2/x )y=0  on  0<x<infty

the boundary conditions being that y should remain bounded as x
tends to 0 and x tends to infty. The coding of this problem is
discussed in detail in Section 8.5.

The choice of matching point c is open. If we choose c=30.0 as in
the D02KDF(*) example program we find that the exponentially
increasing component of the solution dominates and we get
extremely inaccurate values for the eigenfunction (though the
eigenvalue is determined accurately). The values of the
eigenfunction calculated with c=30.0 are given schematically in
Figure 2.

                              Figure 2
         Please see figure in printed Reference Manual

If we choose c as the maximum of the hump in q(x;(lambda)) (see
(a) above) we instead obtain the accurate results given in
Figure 3.

                              Figure 3
```

Please see figure in printed Reference Manual

8.4. Examples of Coding the COEFFN Routine

Coding COEFFN is straightforward except when break-points are needed. The examples below show:

(a) a simple case,

(b) a case in which discontinuities in the coefficient functions or their derivatives necessitate break-points, and

(c) a case where break-points together with the HMAX parameter are an efficient way to deal with a coefficient function that is well-behaved except over one short interval.

Example A

The modified Bessel equation

$$x(xy')'+((lambda)x^2-(nu)^2)y=0$$

Assuming the interval of solution does not contain the origin, dividing through by x, we have p(x)=x, $q(x;(lambda))=(lambda)x-(nu)^2/x$. The code could be

```
      SUBROUTINE COEFFN(P,Q,DQDL,X,ELAM,JINT)
      P = X
      Q = ELAM*X + NU*NU/X
      DQDL = X
      RETURN
      END
```

where NU (standing for (nu)) is a real variable that might be defined in a DATA statement, or might be in user-declared COMMON so that its value could be set in the main program.

Example B

The Schroedinger equation

$$y''+((lambda)+q(x))y=0$$

$\{ x^2 -10 \ (|x|<=4),$

where q(x)={6/|x| (|x|>4),

over some interval 'approximating to (-infty,infty)', say [-20, 20]. Here we need break-points at +- 4, forming three sub-intervals i_1 =[-20,-4], i_2 =[-4,4],i_3 =[4,20]. The code could be

```
      SUBROUTINE COEFFN(P,Q,DQDL,X,ELAM,JINT)
      IF (JINT.EQ.2) THEN
        Q = ELAM + X*X - 10.0E0
      ELSE
        Q = ELAM + 6.0E0/ABS(X)
      ENDIF
      P = 1.0E0
      DQDL = 1.0E0
      RETURN
      END
```

The array XPOINT would contain the values x_1, -20.0, -4.0, +4.0, +20.0, x_6 and m would be 6. The choice of appropriate values for x_1 and x_6 depends on the form of the asymptotic formula computed by BDYVAL and the technique is discussed in the next subsection.

Example C

$$y''+(\lambda)(1-2e^{-100x^2})y=0, \text{ over } -10<=x<=10$$

Here q(x;(lambda)) is nearly constant over the range except for a sharp inverted spike over approximately -0.1<=x<=0.1. There is a danger that the routine will build up to a large step size and 'step over' the spike without noticing it. By using break-points - say at +- 0.5 - one can restrict the step size near the spike without impairing the efficiency elsewhere.

The code for COEFFN could be

```
      SUBROUTINE COEFFN(P,Q,DQDL,X,ELAM,JINT)
      P = 1.0E0
      DQDL = 1.0E0 - 2.0E0*EXP(-100.0E0*X*X)
      Q = ELAM*DQDL
      RETURN
      END
```

XPOINT might contain -0.0, -10.0, -0.5, 0.5, 10.0, 10.0 (assuming +- 10 are regular points) and m would be 6. HMAX(1,j), j=1,2,3 might contain 0.0, 0.1 and 0.0.

8.5. Examples of Boundary Conditions at Singular Points

Quoting from Bailey [2] page 243: 'Usually... the differential equation has two essentially different types of solution near a singular point, and the boundary condition there merely serves to distinguish one kind from the other. This is the case in all the standard examples of mathematical physics.'

In most cases the behaviour of the ratio p(x)y'/y near the point is quite different for the two types of solution. Essentially what the user provides through his BDYVAL routine is an approximation to this ratio, valid as x tends to the singular point (SP).

The user must decide (a) how accurate to make this approximation or asymptotic formula, for example how many terms of a series to use, and (b) where to place the boundary matching point (BMP) at which the numerical solution of the differential equation takes over from the asymptotic formula. Taking the BMP closer to the SP will generally improve the accuracy of the asymptotic formula, but will make the computation more expensive as the Pruefer differential equations generally become progressively more ill-behaved as the SP is approached. The user is strongly recommended to experiment with placing the BMPs. In many singular problems quite crude asymptotic formulae will do. To help the user avoid needlessly accurate formulae, D02KEF outputs two 'sensitivity coefficients' (sigma) ,(sigma) which estimate how much the
```
                     l        r
```
errors at the BMP's affect the computed eigenvalue. They are described in detail below, see Section 8.6.

Example of coding BDYVAL:

The example below illustrates typical situations:

```
                 (            2 )
             y''+((lambda)-x- --)y=0, for 0<x<infty
                 (             2)
                 (            x )
```

the boundary conditions being that y should remain bounded as x tends to 0 and x tends to infty.

At the end x=0 there is one solution that behaves like x^2 and another that behaves like x^{-1}. For the first of these solutions p(x)y'/y is asymptotically 2/x while for the second it is asymptotically -1/x. Thus the desired ratio is specified by setting

YL(1)=x and YL(2)=2.0.

At the end x=infty the equation behaves like Airy's equation shifted through (lambda), i.e., like y''-ty=0 where t=x-(lambda), so again there are two types of solution. The solution we require behaves as

$$\exp\left(-\frac{2}{3}t^{3/2}\right)/\sqrt[4]{t}$$

and the other as

$$\exp\left(+\frac{2}{3}t^{3/2}\right)/\sqrt[4]{t}$$

once, the desired solution has $p(x)y'/y\sim-\sqrt{t}$ so that we could set

YR(1) = 1.0 and YR(2)=$-\sqrt{x-(\lambda)}$. The complete subroutine might thus be

```
      SUBROUTINE BDYVAL(XL,XR,ELAM,YL,YR)
      real XL, XR, ELAM, YL(3), YR(3)
      YL(1) = XL
      YL(2) = 2.0E0
      YR(1) = 1.0E0
      YR(2) = -SQRT(XR - ELAM)
      RETURN
      END
```

Clearly for this problem it is essential that any value given by D02KEF to XR is well to the right of the value of ELAM, so that the user must vary the right-hand BMP with the eigenvalue index k $_k$
function Ai(x), so there is no problem in estimating ELAM.

More accurate asymptotic formulae are easily found - near x=0 by the standard Frobenius method, and near x=infty by using standard asymptotics for Ai(x), Ai'(x) (see [1], p. 448). For example, by the Frobenius method the solution near x=0 has the expansion

$$y=x^2(c_0+c_1x+c_2x^2+...)$$

with

$$c_0=1,c_1=0,c_2=-\frac{\lambda}{10},c_3=\frac{1}{18},...,c_n=\frac{c_{n-3}-\lambda c_{n-2}}{n(n+3)}$$

This yields

$$\frac{p(x)y'}{y}=\frac{2-\frac{2}{5}\lambda x^2+...}{x\left(1-\frac{\lambda}{10}x^2+...\right)}.$$

8.6. The Sensitivity Parameters σ_l and σ_r

The sensitivity parameters σ_l,σ_r (held in HMAX(1,m-1) and HMAX(1,m) on output) estimate the effect of errors in the boundary conditions. For sufficiently small errors Δy, $\Delta py'$ in y and py' respectively, the relations

$$\Delta\lambda \simeq (y.\Delta py'-py'.\Delta y)_l \sigma_l$$

$$\Delta\lambda \simeq (y.\Delta py'-py'.\Delta y)_r \sigma_r$$

are satisfied where the subscripts l, r denote errors committed at left- and right-hand BMP's respectively, and $\Delta\lambda$ denotes the consequent error in the computed eigenvalue.

8.7. Missed Zeros

This is a pitfall to beware of at a singular point. If the BMP is chosen so far from the SP that a zero of the desired eigenfunction lies in between them, then the routine will fail to number of zeros of its eigenfunction, the result will be that:

```
    (a)   The wrong eigenvalue will be computed for the given index k
          - in fact some (lambda)     will be found where k'>=1.
                                 k+k'

    (b)   The same index k can cause convergence to any of several
          eigenvalues depending on the initial values of ELAM and
          DELAM.

     It is up to the user to take suitable precautions - for instance
     by varying the position of the BMP's in the light of his
     knowledge of the asymptotic behaviour of the eigenfunction at
     different eigenvalues.

     9. Example

     To find the 11th eigenvalue and eigenfunction of the example of
     Section 8.5, using the simple asymptotic formulae for the
     boundary conditions.

     Comparison of the results from this example program with the
     corresponding results from D02KDF(*) example program shows that
     similar output is produced from the routine MONIT, followed by
     the eigenfunction values from REPORT, and then a further line of
     information from MONIT (corresponding to the integration to find
     the eigenfunction). Final information is printed within the
     example program exactly as with D02KDF(*).

                                                 3 _
     Note the discrepancy at the matching point c(=\/4 , the maximum
     of q(x;(lambda)), in this case) between the solutions obtained by
     integrations from left and right end-points.

     The example program is not reproduced here. The source code for
     all example programs is distributed with the NAG Foundation
     Library software and should be available on-line.

     D02RAF(3NAG)      Foundation Library (12/10/92)      D02RAF(3NAG)

          D02 -- Ordinary Differential Equations                    D02RAF
                  D02RAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          D02RAF solves the two-point boundary-value problem with general
          boundary conditions for a system of ordinary differential
          equations, using a deferred correction technique and Newton
          iteration.

          2. Specification

                 SUBROUTINE D02RAF (N, MNP, NP, NUMBEG, NUMMIX, TOL, INIT,
                1                   X, Y, IY, ABT, FCN, G, IJAC, JACOBF,
                2                   JACOBG, DELEPS, JACEPS, JACGEP, WORK,
                3                   LWORK, IWORK, LIWORK, IFAIL)
                 INTEGER          N, MNP, NP, NUMBEG, NUMMIX, INIT, IY,
                1                 IJAC, LWORK, IWORK(LIWORK), LIWORK, IFAIL
                 DOUBLE PRECISION TOL, X(MNP), Y(IY,MNP), ABT(N), DELEPS,
                1                 WORK(LWORK)
                 EXTERNAL         FCN, G, JACOBF, JACOBG, JACEPS, JACGEP

          3. Description

          D02RAF solves a two-point boundary-value problem for a system of
          n ordinary differential equations in the interval (a,b) with b>a.
          The system is written in the form

                      y '=f (x,y ,y ,...,y ) , i=1,2,...,n              (1)
                       i   i    1  2      n

          and the derivatives f  are evaluated by a subroutine FCN supplied
                               i
          by the user. With the differential equations (1) must be given a
          system of n (nonlinear) boundary conditions
```

$$g_i(y(a),y(b))=0\ ,\ i=1,2,\ldots,n$$

where

$$y(x)=[y_1(x),y_2(x),\ldots,y_n(x)]^T\ . \qquad (2)$$

The functions g_i are evaluated by a subroutine G supplied by the user. The solution is computed using a finite-difference technique with deferred correction allied to a Newton iteration to solve the finite-difference equations. The technique used is described fully in Pereyra [1].

The user must supply an absolute error tolerance and may also supply an initial mesh for the finite-difference equations and an initial approximate solution (alternatively a default mesh and approximation are used). The approximate solution is corrected using Newton iteration and deferred correction. Then, additional points are added to the mesh and the solution is recomputed with the aim of making the error everywhere less than the user's tolerance and of approximately equidistributing the error on the final mesh. The solution is returned on this final mesh.

If the solution is required at a few specific points then these should be included in the initial mesh. If, on the other hand, the solution is required at several specific points then the user should use the interpolation routines provided in Chapter E01 if these points do not themselves form a convenient mesh.

The Newton iteration requires Jacobian matrices

$$\left(\frac{\partial f_i}{\partial y_j}\right),\ \left(\frac{\partial g_i}{\partial y_j(a)}\right) \text{ and } \left(\frac{\partial g_i}{\partial y_j(b)}\right).$$

These may be supplied by the user through subroutines JACOBF for $\left(\frac{\partial f_i}{\partial y_j}\right)$ and JACOBG for the others. Alternatively the Jacobians may be calculated by numerical differentiation using the algorithm described in Curtis et al [2].

For problems of the type (1) and (2) for which it is difficult to determine an initial approximation from which the Newton iteration will converge, a continuation facility is provided. The user must set up a family of problems

$$y'=f(x,y,(epsilon)), \quad g(y(a),y(b),(epsilon))=0, \qquad (3)$$

where $f=[f_1,f_2,...,f_n]^T$ etc, and where (epsilon) is a continuation parameter. The choice (epsilon)=0 must give a problem (3) which is easy to solve and (epsilon)=1 must define the problem whose solution is actually required. The routine solves a sequence of problems with (epsilon) values

$$0=(epsilon)_1<(epsilon)_2<...<(epsilon)_p=1. \qquad (4)$$

The number p and the values $(epsilon)_i$ are chosen by the routine so that each problem can be solved using the solution of its predecessor as a starting approximation. Jacobians $\frac{ddf}{dd(epsilon)}$ and $\frac{ddg}{dd(epsilon)}$ are required and they may be supplied by the user via routines JACEPS and JACGEP respectively or may be computed by numerical differentiation.

5. Parameters

1: N -- INTEGER Input
On entry: the number of differential equations, n.
Constraint: N > 0.

2: MNP -- INTEGER Input
On entry: MNP must be set to the maximum permitted number

of points in the finite-difference mesh. If LWORK or LIWORK (see below) is too small then internally MNP will be replaced by the maximum permitted by these values. (A warning message will be output if on entry IFAIL is set to obtain monitoring information.) Constraint: MNP >= 32.

3: NP -- INTEGER Input/Output
On entry: NP must be set to the number of points to be used in the initial mesh. Constraint: 4 <= NP <= MNP. On exit: the number of points in the final mesh.

4: NUMBEG -- INTEGER Input
On entry: the number of left-hand boundary conditions (that is the number involving y(a) only). Constraint: 0 <= NUMBEG < N.

5: NUMMIX -- INTEGER Input
On entry: the number of coupled boundary conditions (that is the number involving both y(a) and y(b)). Constraint: 0 <= NUMMIX <= N - NUMBEG.

6: TOL -- DOUBLE PRECISION Input
On entry: a positive absolute error tolerance. If

$$a=x_1<x_2<\ldots<x_{NP}=b$$

is the final mesh, $z_j(x_i)$ is the jth component of the approximate solution at x_i, and $y_j(x)$ is the jth component of the true solution of (1) and (2), then, except in extreme circumstances, it is expected that

$$|z_j(x_i)-y_j(x_i)|\le TOL, \quad i=1,2,\ldots,NP; \; j=1,2,\ldots,n. \qquad (5)$$

Constraint: TOL > 0.0.

7: INIT -- INTEGER Input
On entry: indicates whether the user wishes to supply an initial mesh and approximate solution (INIT /= 0) or whether default values are to be used, (INIT = 0).

8: X(MNP) -- DOUBLE PRECISION array Input/Output
On entry: the user must set X(1) = a and X(NP) = b. If INIT = 0 on entry a default equispaced mesh will be used, otherwise the user must specify a mesh by setting X(i)=x_i, for i = 2,3,...NP-1. Constraints:

X(1) < X(NP), if INIT = 0,

X(1) < X(2) <... < X(NP), if INIT /= 0.

On exit: X(1),X(2),...,X(NP) define the final mesh (with

```
    the returned value of NP) and X(1) = a and X(NP) = b.

 9: Y(IY,MNP) -- DOUBLE PRECISION array            Input/Output
    On entry: if INIT = 0, then Y need not be set.

    If INIT /= 0, then the array Y must contain an initial
    approximation to the solution such that Y(j,i) contains an
    approximation to
                y (x ) , i=1,2,...,NP ; j=1,2,...,n.
                 j  i
    On exit: the approximate solution z (x ) satisfying (5) on
                                       j  i
    the final mesh, that is
            Y(j,i)=z (x ) , i=1,2,...,NP ; j=1,2,...,n,
                    j  i
    where NP is the number of points in the final mesh. If an
    error has occurred then Y contains the latest approximation
    to the solution. The remaining columns of Y are not used.

10: IY -- INTEGER                                         Input
    On entry:
    the first dimension of the array Y as declared in the
    (sub)program from which D02RAF is called.
    Constraint: IY >= N.

11: ABT(N) -- DOUBLE PRECISION array                     Output
    On exit: ABT(i), for i=1,2,...,n, holds the largest
    estimated error (in magnitude) of the ith component of the
    solution over all mesh points.

12: FCN -- SUBROUTINE, supplied by the user.
                                             External Procedure
    FCN must evaluate the functions f  (i.e., the derivatives
                                     i
    y' ) at a general point x for a given value of (epsilon),
      i
    the continuation parameter (see Section 3).

    Its specification is:

           SUBROUTINE FCN (X, EPS, Y, F, N)
           INTEGER          N
           DOUBLE PRECISION X, EPS, Y(N), F(N)

     1:  X -- DOUBLE PRECISION                            Input
         On entry: the value of the argument x.

     2:  EPS -- DOUBLE PRECISION                          Input
         On entry: the value of the continuation parameter,
         (epsilon). This is 1 if continuation is not being used.
     3:  Y(N) -- DOUBLE PRECISION array                    Input
         On entry: the value of the argument y , for
                                              i
         i=1,2,...,n.

     4:  F(N) -- DOUBLE PRECISION array                   Output
         On exit: the values of f , for i=1,2,...,n.
                                 i

     5:  N -- INTEGER                                      Input
         On entry: the number of equations.
    FCN must be declared as EXTERNAL in the (sub)program
    from which D02RAF is called. Parameters denoted as
    Input must not be changed by this procedure.

    13:  G -- SUBROUTINE, supplied by the user.
                                         External Procedure
    G must evaluate the boundary conditions in equation (3) and
    place them in the array BC.

    Its specification is:

           SUBROUTINE G (EPS, YA, YB, BC, N)
           INTEGER          N
           DOUBLE PRECISION EPS, YA(N), YB(N), BC(N)

     1:  EPS -- DOUBLE PRECISION                           Input
         On entry: the value of the continuation parameter,
         (epsilon). This is 1 if continuation is not being used.

     2:  YA(N) -- DOUBLE PRECISION array                   Input
         On entry: the value y (a), for i=1,2,...,n.
                              i

     3:  YB(N) -- DOUBLE PRECISION array                   Input
         On entry: the value y (b), for i=1,2,...,n.
                              i

     4:  BC(N) -- DOUBLE PRECISION array                  Output
         On exit: the values g (y(a),y(b),(epsilon)), for
                              i
         i=1,2,...,n. These must be ordered as follows:
           (i)   first, the conditions involving only y(a) (see
                 NUMBEG description above);

           (ii)  next, the NUMMIX coupled conditions involving
                 both y(a) and y(b) (see NUMMIX description
                 above); and,
       (iii) finally, the conditions involving only y(b) (N-
             NUMBEG-NUMMIX).

   5:  N -- INTEGER                                      Input
       On entry: the number of equations, n.
  G must be declared as EXTERNAL in the (sub)program from
  which D02RAF is called. Parameters denoted as Input
  must not be changed by this procedure.

 14:  IJAC -- INTEGER                                    Input
      On entry: indicates whether or not the user is supplying
      Jacobian evaluation routines. If IJAC /= 0 then the user
      must supply routines JACOBF and JACOBG and also, when
      continuation is used, routines JACEPS and JACGEP. If IJAC =
      0 numerical differentiation is used to calculate the
      Jacobian and the routines D02GAZ, D02GAY, D02GAZ and D02GAX
                                       ( ddf )
                                       (    i)
      JACOBF must evaluate the Jacobian ( ----) for i,j=1,2,...,n,
                                       ( ddy )
                                       (    j)
      given x and y , for j=1,2,...,n.
                   j

      Its specification is:

             SUBROUTINE JACOBF (X, EPS, Y, F, N)
             INTEGER          N
             DOUBLE PRECISION X, EPS, Y(N), F(N,N)

   1:  X -- DOUBLE PRECISION                             Input
       On entry: the value of the argument x.

   2:  EPS -- DOUBLE PRECISION                           Input
       On entry: the value of the continuation parameter
       (epsilon). This is 1 if continuation is not being used.

   3:  Y(N) -- DOUBLE PRECISION array                    Input
       On entry: the value of the argument y , for
                                            i
       i=1,2,...,n.

   4:  F(N,N) -- DOUBLE PRECISION array                 Output
                                                    ddf
                                                      i
       On exit: F(i,j) must be set to the value of   ----,
                                                    ddy
                                                      j
       evaluated at the point (x,y), for i,j=1,2,...,n.
```

```
          5:  N -- INTEGER                                     Input
              On entry: the number of equations, n.
         JACOBF must be declared as EXTERNAL in the (sub)program
         from which D02RAF is called. Parameters denoted as
         Input must not be changed by this procedure.

    16:  JACOBG -- SUBROUTINE, supplied by the user.
                                                  External Procedure
                                          (  ddg   )     (  ddg   )
                                          (      i  )     (      i  )
         JACOBG must evaluate the Jacobians ( -------) and ( -------)
                                          ( ddy (a))     ( ddy (b))
                                          (     j   )     (     j   )
         The ordering of the rows of AJ and BJ must correspond to
         the ordering of the boundary conditions described in the
         specification of subroutine G above.

         Its specification is:

                SUBROUTINE JACOBG (EPS, YA, YB, AJ, BJ, N)
                INTEGER          N
                DOUBLE PRECISION EPS, YA(N), YB(N), AJ(N,N), BJ
               1                 (N,N)

          1:  EPS -- DOUBLE PRECISION                          Input
              On entry: the value of the continuation parameter,
              (epsilon). This is 1 if continuation is not being used.

          2:  YA(N) -- DOUBLE PRECISION array                  Input
              On entry: the value y (a), for i=1,2,...,n.
                                   i

          3:  YB(N) -- DOUBLE PRECISION array                  Input
              On entry: the value y (b), for i=1,2,...,n.
                                   i

          4:  AJ(N,N) -- DOUBLE PRECISION array               Output
                                                      ddg
                                                         i
              On exit: AJ(i,j) must be set to the value  -------,
                                                     ddy (a)
                                                        j
              for i,j=1,2,...,n.

          5:  BJ(N,N) -- DOUBLE PRECISION array               Output
                                                      ddg
                                                         i
              On exit: BJ(i,j) must be set to the value  -------,
                                                     ddy (b)
                                                        j
```

for i,j=1,2...,n.

6: N -- INTEGER Input
On entry: the number of equations, n.

JACOBG must be declared as EXTERNAL in the (sub)program from which D02RAF is called. Parameters denoted as Input must not be changed by this procedure.

17: DELEPS -- DOUBLE PRECISION Input/Output
On entry: DELEPS must be given a value which specifies whether continuation is required. If DELEPS <= 0.0 or DELEPS >= 1.0 then it is assumed that continuation is not required. If 0.0 < DELEPS < 1.0 then it is assumed that continuation is required unless DELEPS < square root of machine precision when an error exit is taken. DELEPS is used as the increment $\text{(epsilon)}_2 - \text{(epsilon)}_1$ (see (4)) and the choice DELEPS = 0.1 is recommended. On exit: an overestimate of the increment $\text{(epsilon)}_p - \text{(epsilon)}_{p-1}$ (in fact the value of the increment which would have been tried if the restriction $\text{(epsilon)}_p = 1$ had not been imposed). If continuation was not requested then DELEPS = 0.0.

If continuation is not requested then the parameters JACEPS and JACGEP may be replaced by dummy actual parameters in the call to D02RAF. (D02GAZ and D02GAX respectively may be used as the dummy parameters.)

18: JACEPS -- SUBROUTINE, supplied by the user. External Procedure

JACEPS must evaluate the derivative $\frac{ddf_i}{dd\text{(epsilon)}}$ given x and y if continuation is being used.

Its specification is:

```
SUBROUTINE JACEPS (X, EPS, Y, F, N)
INTEGER          N
DOUBLE PRECISION X, EPS, Y(N), F(N)
```

1: X -- DOUBLE PRECISION Input
On entry: the value of the argument x.

2: EPS -- DOUBLE PRECISION Input
On entry: the value of the continuation parameter, (epsilon).

3: Y(N) -- DOUBLE PRECISION array Input

On entry: the solution values y_i at the point x, for i=1,2,...,n.

4: F(N) -- DOUBLE PRECISION array Output

On exit: F(i) must contain the value $\frac{ddf_i}{dd(epsilon)}$ at the point (x,y), for i=1,2,...,n.

5: N -- INTEGER Input

On entry: the number of equations, n.

JACEPS must be declared as EXTERNAL in the (sub)program from which D02RAF is called. Parameters denoted as Input must not be changed by this procedure.

19: JACGEP -- SUBROUTINE, supplied by the user. External Procedure

JACGEP must evaluate the derivatives $\frac{ddg_i}{dd(epsilon)}$ if continuation is being used.

Its specification is:

```
SUBROUTINE JACGEP (EPS, YA, YB, BCEP, N)
INTEGER          N
DOUBLE PRECISION EPS, YA(N), YB(N), BCEP(N)
```

1: EPS -- DOUBLE PRECISION Input

On entry: the value of the continuation parameter, (epsilon).

2: YA(N) -- DOUBLE PRECISION array Input

On entry: the value of $y_i(a)$, for i=1,2,...,n.

3: YB(N) -- DOUBLE PRECISION array Input

On entry: the value of $y_i(b)$, for i=1,2,...,n.

4: BCEP(N) -- DOUBLE PRECISION array Output

On exit: BCEP(i) must contain the value of $\frac{ddg_i}{}$, for i=1,2,...,n.

```
           dd(epsilon)

      5:  N -- INTEGER                                    Input
          On entry: the number of equations, n.
     JACGEP must be declared as EXTERNAL in the (sub)program
     from which D02RAF is called. Parameters denoted as
     Input must not be changed by this procedure.

 20: WORK(LWORK) -- DOUBLE PRECISION array            Workspace

 21: LWORK -- INTEGER                                     Input
     On entry:
     the dimension of the array WORK as declared in the
     (sub)program from which D02RAF is called.
                               2         2
     Constraint: LWORK>=MNP*(3N +6N+2)+4N +3N.

 22: IWORK(LIWORK) -- INTEGER array                   Workspace

 23: LIWORK -- INTEGER                                    Input
     On entry:
     the dimension of the array IWORK as declared in the
     (sub)program from which D02RAF is called.
     Constraints:
          LIWORK>=MNP*(2*N+1)+N, if IJAC /= 0,

                               2
          LIWORK>=MNP*(2*N+1)+N +4*N+2, if IJAC = 0.

 24: IFAIL -- INTEGER                              Input/Output
     For this routine, the normal use of IFAIL is extended to
     control the printing of error and warning messages as well
     as specifying hard or soft failure (see the Essential
     Introduction).

     Before entry, IFAIL must be set to a value with the decimal
     expansion cba, where each of the decimal digits c, b and a
     must have a value of 0 or 1.
     a=0   specifies hard failure, otherwise soft failure;

     b=0   suppresses error messages, otherwise error messages
           will be printed (see Section 6);

     c=0   suppresses warning messages, otherwise warning
           messages will be printed (see Section 6).
     The recommended value for inexperienced users is 110 (i.e.,
     hard failure with all messages printed).

     Unless the routine detects an error (see Section 6), IFAIL
     contains 0 on exit.
```

```
6. Error Indicators and Warnings

Errors detected by the routine:

For each error, an explanatory error message is output on the
current error message unit (as defined by X04AAF), unless
suppressed by the value of IFAIL on entry.

IFAIL= 1
     One or more of the parameters N, MNP, NP, NUMBEG, NUMMIX,
     TOL, DELEPS, LWORK or LIWORK has been incorrectly set, or X
     (1) >= X(NP) or the mesh points X(i) are not in strictly
     ascending order.

IFAIL= 2
     A finer mesh is required for the accuracy requested; that is
     MNP is not large enough. This error exit normally occurs
     when the problem being solved is difficult (for example,
     there is a boundary layer) and high accuracy is requested. A
     poor initial choice of mesh points will make this error exit
     more likely.

IFAIL= 3
     The Newton iteration has failed to converge. There are
     several possible causes for this error:
     (i)   faulty coding in one of the Jacobian calculation
           routines;

     (ii)  if IJAC = 0 then inaccurate Jacobians may have been
           calculated numerically (this is a very unlikely
           cause); or,

     (iii) a poor initial mesh or initial approximate solution
           has been selected either by the user or by default or
           there are not enough points in the initial mesh.
           Possibly, the user should try the continuation
           facility.

IFAIL= 4
     The Newton iteration has reached round-off error level. It
     could be however that the answer returned is satisfactory.
     The error is likely to occur if too high an accuracy is
     requested.

IFAIL= 5
     The Jacobian calculated by JACOBG (or the equivalent matrix
     calculated by numerical differentiation) is singular. This
     may occur due to faulty coding of JACOBG or, in some
     circumstances, to a zero initial choice of approximate
     solution (such as is chosen when INIT = 0).

IFAIL= 6
     There is no dependence on (epsilon) when continuation is
     being used. This can be due to faulty coding of JACEPS or
     JACGEP or, in some circumstances, to a zero initial choice
     of approximate solution (such as is chosen when INIT = 0).

IFAIL= 7
     DELEPS is required to be less than machine precision for
     continuation to proceed. It is likely that either the
     problem (3) has no solution for some value near the current
     value of (epsilon) (see the advisory print out from D02RAF)
     or that the problem is so difficult that even with
     continuation it is unlikely to be solved using this routine.
     If the latter cause is suspected then using more mesh points
     initially may help.

IFAIL= 8
     Indicates that a serious error has occurred in a call to
     D02RAF. Check all array subscripts and subroutine parameter
     lists in calls to D02RAF. Seek expert help.

IFAIL= 9
     Indicates that a serious error has occurred in a call to
     D02RAR. Check all array subscripts and subroutine parameter
     lists in calls to D02RAF. Seek expert help.

7. Accuracy

The solution returned by the routine will be accurate to the
user's tolerance as defined by the relation (5) except in extreme
circumstances. The final error estimate over the whole mesh for
each component is given in the array ABT. If too many points are
specified in the initial mesh, the solution may be more accurate
than requested and the error may not be approximately
equidistributed.

8. Further Comments

There are too many factors present to quantify the timing. The
time taken by the routine is negligible only on very simple
problems.

The user is strongly recommended to set IFAIL to obtain self-
explanatory error messages, and also monitoring information about
the course of the computation.

In the case where the user wishes to solve a sequence of similar
problems, the use of the final mesh and solution from one case as
```

```
         the initial mesh is strongly recommended for the next.

         9. Example

         We solve the differential equation

                                                        2
                          y'''=-yy''-2(epsilon)(1-y' )

         with (epsilon)=1 and boundary conditions

                             y(0)=y'(0)=0,  y'(10)=1

         to an accuracy specified by TOL=1.0E-4. The continuation facility
         is used with the continuation parameter (epsilon) introduced as
         in the differential equation above and with DELEPS = 0.1
         initially. (The continuation facility is not needed for this
         problem and is used here for illustration.)

         The example program is not reproduced here. The source code for
         all example programs is distributed with the NAG Foundation
         Library software and should be available on-line.

         D03 -- Partial Differential Equations         Introduction -- D03
                                   Chapter D03
                          Partial Differential Equations
```

1. Scope of the Chapter

This chapter is concerned with the solution of partial differential equations.

2. Background to the Problems

The definition of a partial differential equation problem includes not only the equation itself but also the domain of interest and appropriate subsidiary conditions. Indeed, partial differential equations are usually classified as elliptic, hyperbolic or parabolic according to the form of the equation and the form of the subsidiary conditions which must be assigned to produce a well-posed problem. Ultimately it is hoped that this chapter will contain routines for the solution of equations of each of these types together with automatic mesh generation routines and other utility routines particular to the solution of partial differential equations. The routines in this chapter will often call upon routines from the Linear Algebra Chapter F04 -- Simultaneous Linear Equations.

The classification of partial differential equations is easily described in the case of linear equations of the second order in two independent variables, i.e., equations of the form

$$au_{xx}+2bu_{xy}+cu_{yy}+du_x+eu_y+fu+g=0, \qquad (1)$$

where a, b, c, d, e, f and g are functions of x and y only. Equation (1) is called elliptic, hyperbolic or parabolic according as $ac-b^2$ is positive, negative or zero. Useful definitions of the concepts of elliptic, hyperbolic and parabolic character can also be given for differential equations in more than two independent variables, for systems and for nonlinear differential equations.

For elliptic equations, of which Laplace's equation

$$u_{xx}+u_{yy}=0 \qquad (2)$$

is the simplest example of second order, the subsidiary conditions take the form of boundary conditions, i.e., conditions which provide information about the solution at all points of a closed boundary. For example, if equation (2) holds in a plane domain D bounded by a contour C, a solution u may be sought subject to the condition

$$u=f \quad \text{on } C, \qquad (3)$$

where f is a given function. The condition (3) is known as a Dirichlet boundary condition. Equally common is the Neumann boundary condition

$$u'=g \quad \text{on } C, \tag{4}$$

which is one form of a more general condition

$$u'+fu=g \quad \text{on } C, \tag{5}$$

where u' denotes the derivative of u normal to the contour C and f and g are given functions. Provided that f and g satisfy certain restrictions, condition (5) yields a well-posed boundary value problem for Laplace's equation. In the case of the Neumann problem, one further piece of information, e.g. the value of u at a particular point, is necessary for uniqueness of the solution. Boundary conditions similar to the above are applicable to more general second order elliptic equations, whilst two such conditions are required for equations of fourth order.

For hyperbolic equations, the wave equation

$$u_{tt}-u_{xx}=0 \tag{6}$$

is the simplest example of second order. It is equivalent to a first order system

$$u_t-v_x=0, \quad v_t-u_x=0. \tag{7}$$

The subsidiary conditions may take the form of initial conditions, i.e., conditions which provide information about the solution at points on a suitable open boundary. For example, if equation (6) is satisfied for t>0, a solution u may be sought such that

$$u(x,0)=f(x), \quad u_t(x,0)=g(x), \tag{8}$$

where f and g are given functions. This is an example of an initial value problem, sometimes known as Cauchy's problem.

For parabolic equations, of which the heat conduction equation

$$u_t-u_{xx}=0 \tag{9}$$

is the simplest example, the subsidiary conditions always include some of initial type and may also include some of boundary type. For example, if equation (9) is satisfied for t>0 and 0<x<1, a solution u may be sought such that

$$u(x,0)=f(x), \quad 0<x<1, \tag{10}$$

and

$$u(0,t)=0, \quad u(1,t)=1, \quad t>0. \tag{11}$$

This is an example of a mixed initial/boundary value problem.

For all types of partial differential equations, finite difference methods (Mitchell and Griffiths [5]) and finite element methods (Wait and Mitchell [9]) are the most common means of solution and such methods obviously feature prominently either in this chapter or in the companion NAG Finite Element Library. Many of the utility routines in this chapter are concerned with the solution of the large sparse systems of equations which arise from the finite difference and finite element methods.

Alternative methods of solution are often suitable for special classes of problems. For example, the method of characteristics is the most common for hyperbolic equations involving time and one space dimension (Smith [7]). The method of lines (see Mikhlin and Smolitsky [4]) may be used to reduce a parabolic equation to a (stiff) system of ordinary differential equations, which may be solved by means of routines from Chapter D02 -- Ordinary Differential Equations. Similarly, integral equation or boundary element methods (Jaswon and Symm [3]) are frequently used for elliptic equations. Typically, in the latter case, the solution of a boundary value problem is represented in terms of certain boundary functions by an integral expression which satisfies the differential equation throughout the relevant domain. The boundary functions are obtained by applying the given boundary conditions to this representation. Implementation of this method necessitates discretisation of only the boundary of the domain, the dimensionality of the problem thus being effectively reduced by one. The boundary conditions yield a full system of simultaneous equations, as opposed to the sparse systems yielded by the finite difference and finite element methods, but the full system is usually of much lower order. Solution of this system yields the boundary functions, from which the solution of the problem may be obtained, by quadrature, as and where required.

3. Recommendations on Choice and Use of Routines

The choice of routine will depend first of all upon the type of partial differential equation to be solved. At present no special allowances are made for problems with boundary singularities such as may arise at corners of domains or at points where boundary conditions change. For such problems results should be treated with caution.

Users may wish to construct their own partial differential equation solution software for problems not solvable by the routines described in Sections 3.1 to 3.4 below. In such cases users can employ appropriate routines from the Linear Algebra Chapters to solve the resulting linear systems; see Section 3.5 for further details.

3.1. Elliptic Equations

The routine D03EDF solves a system of seven-point difference equations in a rectangular grid (in two dimensions), using the multigrid iterative method. The equations are supplied by the user, and the seven-point form allows cross-derivative terms to be represented (see Mitchell and Griffiths [5]). The method is particularly efficient for large systems of equations with diagonal dominance.

The routine D03EEF discretises a second-order equation on a two-dimensional rectangular region using finite differences and a seven-point molecule. The routine allows for cross-derivative terms, Dirichlet, Neumann or mixed boundary conditions, and either central or upwind differences. The resulting seven-diagonal difference equations are in a form suitable for passing directly to the multigrid routine D03EDF, although other solution methods could easily be used.

The routine D03FAF, based on the routine HW3CRT from FISHPACK (Swarztrauber and Sweet [8]), solves the Helmholtz equation in a three-dimensional cuboidal region, with any combination of Dirichlet, Neumann or periodic boundary conditions. The method used is based on the fast Fourier transform algorithm, and is likely to be particularly efficient on vector-processing machines.

3.2. Hyperbolic Equations

There are no routines available yet for the solution of these equations.

3.3. Parabolic Equations

There are no routines available yet for the solution of these equations.

But problems in two space dimensions plus time may be treated as a succession of elliptic equations [1], [6] using appropriate D03E- routines or one may use codes from the NAG Finite Element Library.

3.4. Utility Routines

There are no utility routines available yet, but routines are available in the Linear Algebra Chapters for the direct and iterative solution of linear equations. Here we point to some of the routines that may be of use in solving the linear systems that arise from finite difference or finite element approximations to partial differential equation solutions. Chapters F01 and F04 should be consulted for further information and for the routine documents. Decision trees for the solution of linear systems are given in Section 3.5 of the F04 Chapter Introduction.

The following routines allow the direct solution of symmetric positive-definite systems:

Band	F04ACF
Variable band (skyline)	F01MCF and F04MCF
Tridiagonal	F04FAF
Sparse	F01MAF* and F04MAF

(* the parameter DROPTL should be set to zero for F01MAF to give a direct solution)

and the following routines allow the iterative solution of symmetric positive-definite systems:

Sparse (incomplete Cholesky)	F01MAF and F04MBF
Sparse (conjugate gradient)	F04MBF

The latter routine above allows the user to supply a pre-conditioner and also allows the solution of indefinite symmetric systems.

The following routines allow the direct solution of unsymmetric systems:

Band	F01LBF and F04LDF
Almost block-diagonal	F01LHF and F04LHF
Tridiagonal	F01LEF and F04LEF or F04EAF
Sparse	F01BRF (and F01BSF) and F04AXF

and the following routine allows the iterative solution of unsymmetric systems:

Sparse	F04QAF

The above routine allows the user to supply a pre-conditioner and also allows the solution of least-squares systems.

not included in the Foundation Library.

1. Purpose

D03EDF solves seven-diagonal systems of linear equations which arise from the discretization of an elliptic partial differential equation on a rectangular region. This routine uses a multigrid technique.

2. Specification

```
       SUBROUTINE D03EDF (NGX, NGY, LDA, A, RHS, UB, MAXIT, ACC,
      1                   US, U, IOUT, NUMIT, IFAIL)
       INTEGER          NGX, NGY, LDA, MAXIT, IOUT, NUMIT, IFAIL
       DOUBLE PRECISION A(LDA,7), RHS(LDA), UB(NGX*NGY), ACC, US
      1                 (LDA), U(LDA)
```

3. Description

D03EDF solves, by multigrid iteration, the seven-point scheme

$$A^6_{i,j} u_{i-1,j+1} + A^7_{i,j} u_{i,j+1}$$

$$+ A^3_{i,j} u_{i-1,j} + A^4_{i,j} u_{ij} + A^5_{i,j} u_{i+1,j}$$

$$+ A^1_{i,j} u_{i,j-1} + A^2_{i,j} u_{i+1,j-1} = f_{ij},$$

$$i=1,2,\ldots,n_x;\ j=1,2,\ldots,n_y,$$

which arises from the discretization of an elliptic partial differential equation of the form

$$(\alpha)(x,y)U_{xx} + (\beta)(x,y)U_{xy} + (\gamma)(x,y)U_{yy} + (\delta)(x,y)U_x$$

$$+(\epsilon)(x,y)U_y + (\phi)(x,y)U = (\psi)(x,y)$$

and its boundary conditions, defined on a rectangular region. This we write in matrix form as

$$Au=f$$

The algorithm is described in separate reports by Wesseling [2], [3] and McCarthy [1].

Systems of linear equations, matching the seven-point stencil defined above, are solved by a multigrid iteration. An initial estimate of the solution must be provided by the user. A zero guess may be supplied if no better approximation is available.

A 'smoother' based on incomplete Crout decomposition is used to eliminate the high frequency components of the error. A restriction operator is then used to map the system on to a sequence of coarser grids. The errors are then smoothed and prolongated (mapped onto successively finer grids). When the finest cycle is reached, the approximation to the solution is corrected. The cycle is repeated for MAXIT iterations or until the required accuracy, ACC, is reached.

D03EDF will automatically determine the number l of possible coarse grids, 'levels' of the multigrid scheme, for a particular problem. In other words, D03EDF determines the maximum integer l so that n_x and n_y can be expressed in the form

$$n_x=m2^{l-1}+1,\quad n_y=n2^{l-1}+1,\quad \text{with } m>=2 \text{ and } n>=2.$$

It should be noted that the rate of convergence improves significantly with the number of levels used (see McCarthy [1]), so that n_x and n_y should be carefully chosen so that n_x-1 and n_y-1 have factors of the form 2^l, with l as large as possible. For good convergence the integer l should be at least 2.

D03EDF has been found to be robust in application, but being an iterative method the problem of divergence can arise. For a strictly diagonally dominant matrix A

$$|A_{ij}^4| > \sum_{k/=4} |A_{ij}^k|$$

no such problem is foreseen. The diagonal dominance of A is not a necessary condition, but should this condition be strongly violated then divergence may occur. The quickest test is to try the routine.

5. Parameters

1: NGX -- INTEGER Input
On entry: the number of interior grid points in the x-direction, n_x. NGX-1 should preferably be divisible by as high a power of 2 as possible. Constraint: NGX >= 3.

2: NGY -- INTEGER Input
On entry: the number of interior grid points in the y-direction, n_y. NGY-1 should preferably be divisible by as high a power of 2 as possible. Constraint: NGY >= 3.

3: LDA -- INTEGER Input
On entry: the first dimension of the array A as declared in the (sub)program from which D03EDF is called, which must also be a lower bound for the dimensions of the arrays RHS, US and U. It is always sufficient to set LDA>=(4*(NGX+1)*(NGY+1))/3, but slightly smaller values may be permitted, depending on the values of NGX and NGY. If on entry, LDA is too small, an error message gives the minimum permitted value. (LDA must be large enough to allow space for the coarse-grid approximations).

4: A(LDA,7) -- DOUBLE PRECISION array Input/Output
On entry: A(i+(j-1)*NGX,k) must be set to A_{ij}^k, for i = 1,2,...,NGX; j = 1,2,...,NGY and k = 1,2,...,7. On exit: A is overwritten.

5: RHS(LDA) -- DOUBLE PRECISION array Input/Output
On entry: RHS(i+(j-1)*NGX) must be set to f_{ij}, for i = 1,2,...,NGX; j = 1,2,...,NGY. On exit: the first NGX*NGY

```
    elements are unchanged and the rest of the array is used as
    workspace.

6:  UB(NGX*NGY) -- DOUBLE PRECISION array           Input/Output
    On entry: UB(i+(j-1)*NGX) must be set to the initial
    estimate for the solution u  . On exit: the corresponding
                               ij
    component of the residual r=f-Au.

7:  MAXIT -- INTEGER                                       Input
    On entry: the maximum permitted number of multigrid
    iterations. If MAXIT = 0, no multigrid iterations are
    performed, but the coarse-grid approximations and incomplete
    Crout decompositions are computed, and may be output if IOUT
    is set accordingly. Constraint: MAXIT >= 0.

8:  ACC -- DOUBLE PRECISION                                Input
    On entry: the required tolerance for convergence of the
    residual 2-norm:

                              / NGX*NGY
                             /  --        2
                   ||r|| =  /   >      (r )
                        2  /    --       k
                         \/     k=1
    where r=f-Au and u is the computed solution. Note that the
    norm is not scaled by the number of equations. The routine
    will stop after fewer than MAXIT iterations if the residual
    2-norm is less than the specified tolerance. (If MAXIT > 0,
    at least one iteration is always performed.)

    If on entry ACC = 0.0, then the machine precision is used as
    a default value for the tolerance; if ACC > 0.0, but ACC is
    less than the machine precision, then the routine will stop
    when the residual 2-norm is less than the machine precision
    and IFAIL will be set to 4. Constraint: ACC >= 0.0.

9:  US(LDA) -- DOUBLE PRECISION array                     Output
    On exit: the residual 2-norm, stored in element US(1).

10: U(LDA) -- DOUBLE PRECISION array                      Output
    On exit: the computed solution u   is returned in U(i+(j-
                                    ij
    1)*NGX), for i = 1,2,...,NGX; j = 1,2,...,NGY.

11: IOUT -- INTEGER                                        Input
    On entry: controls the output of printed information to the
    advisory message unit as returned by X04ABF:
    IOUT = 0
```

```
      No output.

IOUT = 1
      The solution u  , for i = 1,2,...,NGX; j = 1,2,...
                    ij
      ,NGY.

IOUT = 2
      The residual 2-norm after each iteration, with the
      reduction factor over the previous iteration.

IOUT = 3
      As for IOUT = 1 and IOUT = 2.

IOUT = 4
      As for IOUT = 3, plus the final residual (as returned
      in UB).

IOUT = 5
      As for IOUT = 4, plus the initial elements of A and
      RHS.

IOUT = 6
      As for IOUT = 5, plus the Galerkin coarse grid
      approximations.

IOUT = 7
      As for IOUT = 6, plus the incomplete Crout
      decompositions.

IOUT = 8
      As for IOUT = 7, plus the residual after each
      iteration.
The elements A(p,k), the Galerkin coarse grid approximations
and the incomplete Crout decompositions are output in the
format:
     Y-index = j

     X-index = i A(p,1) A(p,2) A(p,3) A(p,4) A(p,5) A(p,6)
     A(p,7)

     where p=i+(j-1)*NGX, i = 1,2,...,NGX and j = 1,2,...
     ,NGY.
The vectors U(p), UB(p), RHS(p) are output in matrix form
with NGY rows and NGX columns. Where NGX > 10, the NGX
values for a given j-value are produced in rows of 10.
Values of IOUT > 4 may yield considerable amounts of output.
Constraint: 0 <= IOUT <= 8.

12:  NUMIT -- INTEGER                                    Output
```

```
     On exit: the number of iterations performed.

13:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry NGX < 3,

     or       NGY < 3,

     or       LDA is too small,

     or       ACC < 0.0,

     or       MAXIT < 0,

     or       IOUT < 0,

     or       IOUT > 8.

IFAIL= 2
     MAXIT iterations have been performed with the residual 2-
     norm decreasing at each iteration but the residual 2-norm
     has not been reduced to less than the specified tolerance
     (see ACC). Examine the progress of the iteration by setting
     IOUT >= 2.

IFAIL= 3
     As for IFAIL = 2, except that at one or more iterations the
     residual 2-norm did not decrease. It is likely that the
     method fails to converge for the given matrix A.

IFAIL= 4
     On entry ACC is less than the machine precision. The routine
     terminated because the residual norm is less than the
     machine precision.

7. Accuracy
```

See ACC (Section 5).

8. Further Comments

The rate of convergence of this routine is strongly dependent upon the number of levels, l, in the multigrid scheme, and thus the choice of NGX and NGY is very important. The user is advised to experiment with different values of NGX and NGY to see the effect they have on the rate of convergence; for example, using a value such as NGX = 65 ($=2^6+1$) followed by NGX = 64 (for which l = 1).

9. Example

The program solves the elliptic partial differential equation

$$U_{xx} - (\alpha)U_{xy} + U_{yy} = -4, \quad (\alpha)=1.7$$

on the unit square 0<=x,y<=1, with boundary conditions

$$U=0 \text{ on } \begin{cases} x=0, & (0\le y\le 1) \\ y=0, & (0\le x\le 1) \\ y=1, & (0\le x\le 1) \end{cases} \quad U=1 \text{ on } x=1, \quad 0\le y\le 1.$$

For the equation to be elliptic, (alpha) must be less than 2.

The equation is discretized on a square grid with mesh spacing h in both directions using the following approximations:

Please see figure in printed Reference Manual

$$U_{xx} \simeq \frac{1}{h^2}(U_E - 2U_O + U_W)$$

$$U_{yy} \simeq \frac{1}{h^2}(U_N - 2U_O + U_S)$$

$$U_{xy} \simeq \frac{1}{2h^2}(U_N - U_{NW} + U_E - 2U_O + U_W - U_{SE} + U_S).$$

```
         Thus the following equations are solved:

             1                      1
             -(alpha)u        + (1- -(alpha))u
             2        i-1,j+1       2         i,j+1

              1                                           1

         D03 -- Partial Differential Equations                     D03EEF
                 D03EEF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D03EEF discretizes a second order elliptic partial differential equation (PDE) on a rectangular region.

2. Specification

```
       SUBROUTINE D03EEF (XMIN, XMAX, YMIN, YMAX, PDEF, BNDY,
      1                   NGX, NGY, LDA, A, RHS, SCHEME, IFAIL)
       INTEGER          NGX, NGY, LDA, IFAIL
       DOUBLE PRECISION XMIN, XMAX, YMIN, YMAX, A(LDA,7), RHS(LDA)
       CHARACTER*1      SCHEME
       EXTERNAL         PDEF, BNDY
```

3. Description

D03EEF discretizes a second order linear elliptic partial differential equation of the form

$$\alpha(x,y)\frac{\partial^2 U}{\partial x^2}+\beta(x,y)\frac{\partial^2 U}{\partial x\partial y}+\gamma(x,y)\frac{\partial^2 U}{\partial y^2}$$

$$+\delta(x,y)\frac{\partial U}{\partial x}+\epsilon(x,y)\frac{\partial U}{\partial y}+\phi(x,y)U=\psi(x,y) \quad (1)$$

on a rectangular region

$$x_A\le x\le x_B$$

$$y_A\le y\le y_B$$

subject to boundary conditions of the form

$$a(x,y)U+b(x,y)\frac{\partial U}{\partial n}=c(x,y)$$

```
       ddU
where  --- denotes the outward pointing normal derivative on the
       ddn
boundary. Equation (1) is said to be elliptic if

                                                   2
            4(alpha)(x,y)(gamma)(x,y)>=((beta)(x,y))

for all points in the rectangular region. The linear equations
produced are in a form suitable for passing directly to the
multigrid routine D03EDF.

The equation is discretized on a rectangular grid, with n  grid
                                                         x
points in the x-direction and n  grid points in the y-direction.
                               y
The grid spacing used is therefore

                        h =(x -x )/(n -1)
                         x   B  A    x

                        h =(y -y )/(n -1)
                         y   B  A    y

and the co-ordinates of the grid points (x ,y ) are
                                          i  j

                  x =x +(i-1)h ,  i=1,2,...,n ,
                   i  A       x              x

                  y =y +(j-1)h ,  j=1,2,...,n .
                   j  A       y              y

At each grid point (x ,y ) six neighbouring grid points are used
                     i  j
to approximate the partial differential equation, so that the
equation is discretized on the following seven-point stencil:

         Please see figure in printed Reference Manual

For convenience the approximation u   to the exact solution
                                   ij
U(x ,y ) is denoted by u , and the neighbouring approximations
   i  j                 O
are labelled according to points of the compass as shown. Where
numerical labels for the seven points are required, these are
also shown above.
```

The following approximations are used for the second derivatives:

```
       2
     dd U   1
     ----~= --(u -2u +u )
       2     2  E   O  W
     dd x   h
             x

       2
     dd U   1
     ----~= --(u -2u +u )
       2     2  N   O  S
     dd y   h
             y

        2
      dd U    1
     ------~= -----(u -u  +u -2u +u -u  +u ).
     ddxddy 2h h   N  NW  E   O  W  SE  S
               x y
```

Two possible schemes may be used to approximate the first derivatives:

Central Differences

```
     ddU     1
     ---~=  ---(u -u )
     ddx    2h   W  E
              x

     ddU     1
     ---~=  ---(u -u )
     ddy    2h   N  S
              y
```

Upwind Differences

```
     ddU    1
     ---~=  --(u -u )if (delta)(x,y)>0
     ddx    h   E  O
             x

     ddU    1
     ---~=  --(u -u )if (delta)(x,y)<0
     ddx    h   O  W
             x

     ddU    1
     ---~=  --(u -u )if (epsilon)(x,y)>0
     ddy    h   N  O
             y

     ddU    1
     ---~=  --(u -u )if (epsilon)(x,y)<0.
     ddy    h   O  S
             y
```

Central differences are more accurate than upwind differences,
but upwind differences may lead to a more diagonally dominant
matrix for those problems where the coefficients of the first
derivatives are significantly larger than the coefficients of the
second derivatives.

The approximations used for the first derivatives may be written
in a more compact form as follows:

```
     ddU     1
     ---~=  ---((k -1)u -2k u +(k +1)u )
     ddx    2h (  x    W   x O   x    E)
              x

     ddU     1
     ---~=  ---((k -1)u -2k u +(k +1)u )
     ddy    2h (  y    S   y O   y    N)
              y
```

```
where k =sign (delta) and k =sign (epsilon) for upwind
       x                   y
differences, and k =k =0 for central differences.
                  x  y
```

At all points in the rectangular domain, including the boundary,
the coefficients in the partial differential equation are
evaluated by calling the user-supplied subroutine PDEF, and
applying the approximations. This leads to a seven-diagonal
system of linear equations of the form:

```
    6            7
   A  u        +A  u
    ij i-1,j+1   ij i,j+1
     3         4       5
   +A  u      +A  u   +A  u
     ij i-1,j   ij ij   ij i+1,j
       1         2
     +A  u      +A  u         =f  , i=1,2,...,n ;j=1,2,...,n ,
       ij i,j-1   ij i+1,j-1   ij             x            y
```

where the coefficients are given by

```
 1                 1                   1                   1
A  =(beta)(x ,y )----- +(gamma)(x ,y )-- +(epsilon)(x ,y )---(k -1)
 ij         i  j 2h h            i  j  2             i  j 2h   y
                   x y                h                     y
                                       y
 2                   1
A  =-(beta)(x ,y ) -----
 ij          i  j   2h h
                     x y

 3                 1                  1                   1
A  =(alpha)(x ,y ) --+(beta)(x ,y ) -----+(delta)(x ,y ) ---(k -1)
 ij          i  j   2         i  j  2h h           i  j  2h   x
                   h                  x y                  x
                    x

 4                  2                  1                   2
A  =-(alpha)(x ,y ) -- -(beta)(x ,y ) ---- -(gamma)(x ,y ) --
 ij           i  j   2          i  j  h h           i  j   2
                    h                  x y                 h
                     x                                      y

                    k                    k
                     y                    y
    -(delta)(x ,y ) -- -(epsilon)(x ,y ) -- -(phi)(x ,y )
              i  j  h              i  j  h          i  j
                     x                    y

 5                 1                  1                   1
A  =(alpha)(x ,y ) --+(beta)(x ,y ) -----+(delta)(x ,y ) ---(k +1)
 ij          i  j   2         i  j  2h h           i  j  2h   x
                   h                  x y                  x
                    x

 6                   1
A  =-(beta)(x ,y ) -----
 ij          i  j   2h h
                     x y

 7                 1                  1                   1
A  =(beta)(x ,y )-----+(gamma)(x ,y )--+(epsilon)(x ,y )---(k +1)
 ij         i  j 2h h           i  j  2             i j 2h   y
                   x y               h                    y
                                      y

f  =(psi)(x ,y )
 ij        i  j
```

These equations then have to be modified to take account of the boundary conditions. These may be Dirichlet (where the solution is given), Neumann (where the derivative of the solution is given), or mixed (where a linear combination of solution and derivative is given).

If the boundary conditions are Dirichlet, there are an infinity of possible equations which may be applied:

$$(\mu)u_{ij}=(\mu)f_{ij}\,,\ (\mu)\neq 0. \qquad (2)$$

If D03EDF is used to solve the discretized equations, it turns out that the choice of (mu) can have a dramatic effect on the rate of convergence, and the obvious choice (mu)=1 is not the best. Some choices may even cause the multigrid method to fail altogether. In practice it has been found that a value of the same order as the other diagonal elements of the matrix is best, and the following value has been found to work well in practice:

$$(\mu)=\min_{ij}\left(-\left\{\frac{2}{h_x^2}+\frac{2}{h_y^2}\right\},A_{ij}^{4}\right).$$

If the boundary conditions are either mixed or Neumann (i.e., B /= 0 on return from the user-supplied subroutine BNDY), then one of the points in the seven-point stencil lies outside the domain. In this case the normal derivative in the boundary conditions is used to eliminate the 'fictitious' point, $u_{outside}$:

$$\frac{\partial U}{\partial n}\simeq\frac{1}{2h}(u_{outside}-u_{inside}). \qquad (3)$$

It should be noted that if the boundary conditions are Neumann and (phi)(x,y)==0, then there is no unique solution. The routine returns with IFAIL = 5 in this case, and the seven-diagonal matrix is singular.

The four corners are treated separately. The user-supplied subroutine BNDY is called twice, once along each of the edges meeting at the corner. If both boundary conditions at this point are Dirichlet and the prescribed solution values agree, then this value is used in an equation of the form (2). If the prescribed solution is discontinuous at the corner, then the average of the two values is used. If one boundary condition is Dirichlet and the other is mixed, then the value prescribed by the Dirichlet condition is used in an equation of the form given above.

Finally, if both conditions are mixed or Neumann, then two 'fictitious' points are eliminated using two equations of the form (3).

It is possible that equations for which the solution is known at all points on the boundary, have coefficients which are not defined on the boundary. Since this routine calls the user-supplied subroutine PDEF at all points in the domain, including boundary points, arithmetic errors may occur in the user's routine PDEF which this routine cannot trap. If the user has an equation with Dirichlet boundary conditions (i.e., B = 0 at all points on the boundary), but with PDE coefficients which are singular on the boundary, then D03EDF could be called directly only using interior grid points with the user's own discretization.

After the equations have been set up as described above, they are checked for diagonal dominance. That is to say,

$$|A^4_{ij}| > \sum_{k/=4} |A^k_{ij}|, \quad i=1,2,...,n_x ; j=1,2,...,n_y .$$

If this condition is not satisfied then the routine returns with IFAIL = 6. The multigrid routine D03EDF may still converge in this case, but if the coefficients of the first derivatives in the partial differential equation are large compared with the coefficients of the second derivative, the user should consider using upwind differences (SCHEME = 'U').

Since this routine is designed primarily for use with D03EDF, this document should be read in conjunction with the document for that routine.

5. Parameters

1: XMIN -- DOUBLE PRECISION Input

2: XMAX -- DOUBLE PRECISION Input
On entry: the lower and upper x co-ordinates of the rectangular region respectively, x_A and x_B . Constraint: XMIN < XMAX.

```
3:  YMIN -- DOUBLE PRECISION                               Input

4:  YMAX -- DOUBLE PRECISION                               Input
    On entry: the lower and upper y co-ordinates of the
    rectangular region respectively, y  and y . Constraint: YMIN
                                      A      B
    < YMAX.

5:  PDEF -- SUBROUTINE, supplied by the user.
                                             External Procedure
    PDEF must evaluate the functions (alpha)(x,y), (beta)(x,y),
    (gamma)(x,y), (delta)(x,y), (epsilon)(x,y), (phi)(x,y) and
    (psi)(x,y) which define the equation at a general point
    (x,y).

    Its specification is:

           SUBROUTINE PDEF (X, Y, ALPHA, BETA, GAMMA,
          1                 DELTA, EPSLON, PHI, PSI)
           DOUBLE PRECISION X, Y, ALPHA, BETA, GAMMA, DELTA,
          1                 EPSLON, PHI, PSI

     1:  X -- DOUBLE PRECISION                             Input

     2:  Y -- DOUBLE PRECISION                             Input
         On entry: the x and y co-ordinates of the point at
         which the coefficients of the partial differential
         equation are to be evaluated. 8

     3:  ALPHA -- DOUBLE PRECISION                        Output

     4:  BETA -- DOUBLE PRECISION                         Output

     5:  GAMMA -- DOUBLE PRECISION                        Output

     6:  DELTA -- DOUBLE PRECISION                        Output

     7:  EPSLON -- DOUBLE PRECISION                       Output

     8:  PHI -- DOUBLE PRECISION                          Output

     9:  PSI -- DOUBLE PRECISION                          Output
         On exit: ALPHA, BETA, GAMMA, DELTA, EPSLON, PHI and PSI
         must be set to the values of (alpha)(x,y), (beta)(x,y),
         (gamma)(x,y), (delta)(x,y), (epsilon)(x,y), (phi)(x,y)
         and (psi)(x,y) respectively at the point specified by X
         and Y.
    PDEF must be declared as EXTERNAL in the (sub)program
    from which D03EEF is called. Parameters denoted as
    Input must not be changed by this procedure.

6:  BNDY -- SUBROUTINE, supplied by the user.
                                              External Procedure
    BNDY must evaluate the functions a(x,y), b(x,y), and c(x,y)
    involved in the boundary conditions.

    Its specification is:

           SUBROUTINE BNDY (X, Y, A, B, C, IBND)
           INTEGER          IBND
           DOUBLE PRECISION X, Y, A, B, C

     1:  X -- DOUBLE PRECISION                             Input

     2:  Y -- DOUBLE PRECISION                             Input
         On entry: the x and y co-ordinates of the point at
         which the boundary conditions are to be evaluated.

     3:  A -- DOUBLE PRECISION                            Output

     4:  B -- DOUBLE PRECISION                            Output

     5:  C -- DOUBLE PRECISION                            Output
         On exit: A, B and C must be set to the values of the
         functions appearing in the boundary conditions.

     6:  IBND -- INTEGER                                   Input
         On entry: specifies on which boundary the point (X,Y)
         lies. IBND = 0, 1, 2 or 3 according as the point lies
         on the bottom, right, top or left boundary.
    BNDY must be declared as EXTERNAL in the (sub)program
    from which D03EEF is called. Parameters denoted as
    Input must not be changed by this procedure.

7:  NGX -- INTEGER                                         Input

8:  NGY -- INTEGER                                         Input
    On entry: the number of interior grid points in the x- and y
    -directions respectively, n  and n . If the seven-diagonal
                               x      y
    equations are to be solved by D03EDF, then NGX-1 and NGY-1
    should preferably be divisible by as high a power of 2 as
    possible. Constraint: NGX >= 3, NGY >= 3.

9:  LDA -- INTEGER                                         Input
    On entry:
    the first dimension of the array A as declared in the
    (sub)program from which D03EEF is called.
    Constraint: if only the seven-diagonal equations are
```

```
        required, then LDA >= NGX*NGY. If a call to this routine is
        to be followed by a call to D03EDF to solve the seven-
        diagonal linear equations, LDA >= (4*(NGX+1)*(NGY+1))/3.

        Note: this routine only checks the former condition. D03EDF,
        if called, will check the latter condition.

   10:  A(LDA,7) -- DOUBLE PRECISION array                     Output
        On exit: A(i,j), for i=1,2,...,NGX*NGY; j = 1,2,...,7,
        contains the seven-diagonal linear equations produced by the
        discretization described above. If LDA > NGX*NGY, the
        remaining elements are not referenced by the routine, but if
        LDA >= (4*(NGX+1)*(NGY+1))/3 then the array A can be passed
        directly to D03EDF, where these elements are used as
        workspace.

   11:  RHS(LDA) -- DOUBLE PRECISION array                     Output
        On exit: the first NGX*NGY elements contain the right-hand
        sides of the seven-diagonal linear equations produced by the
        discretization described above. If LDA > NGX*NGY, the
        remaining elements are not referenced by the routine, but if
        LDA >= (4*(NGY+1)*(NGY+1))/3 then the array RHS can be
        passed directly to D03EDF, where these elements are used as
        workspace.

   12:  SCHEME -- CHARACTER*1                                   Input
        On entry: the type of approximation to be used for the first
        derivatives which occur in the partial differential
        equation.

        If SCHEME = 'C', then central differences are used.

        If SCHEME = 'U', then upwind differences are used.
        Constraint: SCHEME = 'C' or 'U'.

        Note: generally speaking, if at least one of the
        coefficients multiplying the first derivatives (DELTA or
        EPSLON as returned by PDEF) are large compared with the
        coefficients multiplying the second derivatives, then upwind
        differences may be more appropriate. Upwind differences are
        less accurate than central differences, but may result in
        more rapid convergence for strongly convective equations.
        The easiest test is to try both schemes.

   13:  IFAIL -- INTEGER                                 Input/Output
        On entry: IFAIL must be set to 0, -1 or 1. Users who are
        unfamiliar with this parameter should refer to the Essential
        Introduction for details.

        On exit: IFAIL = 0 unless the routine detects an error or
```

```
     gives a warning (see Section 6).

     For this routine, because the values of output parameters
     may be useful even if IFAIL /=0 on exit, users are
     recommended to set IFAIL to -1 before entry. It is then
     essential to test the value of IFAIL on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry XMIN >= XMAX,

     or       YMIN >= YMAX,

     or       NGX < 3,

     or       NGY < 3,

     or       LDA < NGX*NGY,

     or       SCHEME is not one of 'C' or 'U'.

IFAIL= 2
     At some point on the boundary there is a derivative in the
     boundary conditions (B /= 0 on return from a BNDY) and there
                                                          2
                                                         dd U
     is a non-zero coefficient of the mixed derivative  ------
                                                        ddxddy
     (BETA /= 0 on return from PDEF).

IFAIL= 3
     A null boundary has been specified, i.e., at some point both
     A and B are zero on return from a call to BNDY.

IFAIL= 4
                                                          2
     The equation is not elliptic, i.e., 4*ALPHA*GAMMA<BETA  after
     a call to PDEF. The discretization has been completed, but
     the convergence of D03EDF cannot be guaranteed.

IFAIL= 5
     The boundary conditions are purely Neumann (only the
     derivative is specified) and there is, in general, no unique
     solution.
```

```
          IFAIL= 6
               The equations were not diagonally dominant. (See Section 3).

          7. Accuracy

          Not applicable.

          8. Further Comments

          If this routine is used as a pre-processor to the multigrid
          routine D03EDF it should be noted that the rate of convergence of
          that routine is strongly dependent upon the number of levels in
          the multigrid scheme, and thus the choice of NGX and NGY is very
          important.

          9. Example

          The program solves the elliptic partial differential equation

                             2     2
                           dd U  dd U   { ddU  ddU}
                           ----+ ----+50{ ---+ ---}=f(x,y)
                              2     2   { ddx  ddy}
                           ddx   ddy

          on the unit square 0<=x, y<=1, with boundary conditions

                ddU
                --- given on x=0 and y=0,
                ddn

               U given on x=1 and y=1.

          The function f(x,y) and the exact form of the boundary conditions
          are derived from the exact solution U(x,y)=sinxsiny.

          The equation is first solved using central differences. Since the
          coefficients of the first derivatives are large, the linear
          equations are not diagonally dominated, and convergence is slow.
          The equation is solved a second time with upwind differences,
          showing that convergence is more rapid, but the solution is less
          accurate.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

     D03FAF(3NAG)      Foundation Library (12/10/92)      D03FAF(3NAG)

          D03 -- Partial Differential Equations                      D03FAF
                  D03FAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          D03FAF solves the Helmholtz equation in Cartesian co-ordinates in
          three dimensions using the standard seven-point finite difference
          approximation. This routine is designed to be particularly
          efficient on vector processors.

          2. Specification

                 SUBROUTINE D03FAF (XS, XF, L, LBDCND, BDXS, BDXF, YS, YF,
                1                   M, MBDCND, BDYS, BDYF, ZS, ZF, N,
                2                   NBDCND, BDZS, BDZF, LAMBDA, LDIMF,
                3                   MDIMF, F, PERTRB, W, LWRK, IFAIL)
                 INTEGER          L, LBDCND, M, MBDCND, N, NBDCND, LDIMF,
                1                 MDIMF, LWRK, IFAIL
                 DOUBLE PRECISION XS, XF, BDXS(MDIMF,N+1), BDXF(MDIMF,N+1),
                1                 YS, YF, BDYS(LDIMF,N+1), BDYF(LDIMF,N+1),
                2                 ZS, ZF, BDZS(LDIMF,M+1), BDZF(LDIMF,M+1),
                3                 LAMBDA, F(LDIMF,MDIMF,N+1), PERTRB, W
                4                 (LWRK)
```

3. Description

D03FAF solves the three-dimensional Helmholtz equation in cartesian co-ordinates:

```
  2     2     2
dd u  dd u  dd u
----+ ----+ ----+(lambda)u=f(x,y,z)
  2     2     2
dd x  dd y  dd z
```

This subroutine forms the system of linear equations resulting from the standard seven-point finite difference equations, and then solves the system using a method based on the fast Fourier transform (FFT) described by Swarztrauber [1]. This subroutine is based on the routine HW3CRT from FISHPACK (see Swarztrauber and Sweet [2]).

More precisely, the routine replaces all the second derivatives by second-order central difference approximations, resulting in a block tridiagonal system of linear equations. The equations are modified to allow for the prescribed boundary conditions. Either the solution or the derivative of the solution may be specified on any of the boundaries, or the solution may be specified to be periodic in any of the three dimensions. By taking the discrete Fourier transform in the x- and y-directions, the equations are reduced to sets of tridiagonal systems of equations. The Fourier transforms required are computed using the multiple FFT routines found in Chapter C06 of the NAG Fortran Library.

5. Parameters

```
 1:  XS -- DOUBLE PRECISION                                  Input
     On entry: the lower bound of the range of x, i.e., XS <= x
     <= XF. Constraint: XS < XF.

 2:  XF -- DOUBLE PRECISION                                  Input
     On entry: the upper bound of the range of x, i.e., XS <= x
     <= XF. Constraint: XS < XF.
```

```
3:  L -- INTEGER                                        Input
    On entry: the number of panels into which the interval
    (XS,XF) is subdivided. Hence, there will be L+1 grid points
    in the x-direction given by x =XS+(i-1)*(delta)x, for
                                 i
    i=1,2,...,L+1, where (delta)x=(XF-XS)/L is the panel width.
    Constraint: L >= 5.

4:  LBDCND -- INTEGER                                   Input
    On entry: indicates the type of boundary conditions at x =
    XS and x = XF.
    LBDCND = 0
          if the solution is periodic in x, i.e.,
          u(XS,y,z)=u(XF,y,z).

    LBDCND = 1
          if the solution is specified at x = XS and x = XF.

    LBDCND = 2
          if the solution is specified at x = XS and the
          derivative of the solution with respect to x is
          specified at x = XF.

    LBDCND = 3
          if the derivative of the solution with respect to x is
          specified at x = XS and x = XF.

    LBDCND = 4
          if the derivative of the solution with respect to x is
          specified at x = XS and the solution is specified at x
          = XF.
     Constraint: 0 <= LBDCND <= 4.

5:  BDXS(MDIMF,N+1) -- DOUBLE PRECISION array           Input
    On entry: the values of the derivative of the solution with
    respect to x at x = XS. When LBDCND = 3 or 4, BDXS
    (j,k)=u (XS,y ,z ), for j=1,2,...,M+1; k=1,2,...,N+1.
           x     j  k

    When LBDCND has any other value, BDXS is not referenced.

6:  BDXF(MDIMF,N+1) -- DOUBLE PRECISION array           Input
    On entry: the values of the derivative of the solution with
    respect to x at x = XF. When LBDCND = 2 or 3, BDXF(j,k) =
    u (XF,y ,z ), for j=1,2,...,M+1; k=1,2,...,N+1.
     x     i  k

    When LBDCND has any other value, BDXF is not referenced.

7:  YS -- DOUBLE PRECISION                              Input
```

```
    On entry: the lower bound of the range of y, i.e., YS <= y
    <= YF. Constraint: YS < YF.

 8: YF -- DOUBLE PRECISION                                 Input
    On entry: the upper bound of the range of y, i.e., YS <= y
    <= YF. Constraint: YS < YF.

 9: M -- INTEGER                                           Input
    On entry: the number of panels into which the interval
    (YS,YF) is subdivided. Hence, there will be M+1 grid points
    in the y-direction given by y  = YS + (j-1)*(delta)y for
                                 j
    j=1,2,...,M+1, where (delta)y=(YF-YS)/M is the panel width.
    Constraint: M >= 5.

10: MBDCND -- INTEGER                                      Input
    On entry: indicates the type of boundary conditions at y =
    YS and y = YF.
    MBDCND = 0
          if the solution is periodic in y, i.e.,
          u(x,YF,z)=u(x,YS,z).

    MBDCND = 1
          if the solution is specified at y = YS and y = YF.

    MBDCND = 2
          if the solution is specified at y = YS and the
          derivative of the solution with respect to y is
          specified at y = YF.

    MBDCND = 3
          if the derivative of the solution with respect to y is
          specified at y = YS and y = YF.

    MBDCND = 4
          if the derivative of the solution with respect to y is
          specified at y = YS and the solution is specified at y
          = YF.
     Constraint: 0 <= MBDCND <= 4.

11: BDYS(LDIMF,N+1) -- DOUBLE PRECISION array              Input
    On entry: the values of the derivative of the solution with
    respect to y at y = YS. When MBDCND = 3 or 4, BDYS
    (i,k)=u (x ,y ,z ), for i=1,2,...,L+1; k=1,2,...,N+1.
           y  i  s  k

    When MBDCND has any other value, BDYS is not referenced.

12: BDYF(LDIMF,N+1) -- DOUBLE PRECISION array              Input
    On entry: the values of the derivative of the solution with
```

```
     respect to y at y = YF. When MBDCND = 2 or 3, BDYF
     (i,k)=u (x ,YF,z ), for i=1,2,...,L+1; k=1,2,...,N+1.
            y  i     k

     When MBDCND has any other value, BDYF is not referenced.

13:  ZS -- DOUBLE PRECISION                                 Input
     On entry: the lower bound of the range of z, i.e., ZS <= z
     <= ZF. Constraint: ZS < ZF.

14:  ZF -- DOUBLE PRECISION                                 Input
     On entry: the upper bound of the range of z, i.e., ZS <= z
     <= ZF. Constraint: ZS < ZF.

15:  N -- INTEGER                                           Input
     On entry: the number of panels into which the interval
     (ZS,ZF) is subdivided. Hence, there will be N+1 grid points
     in the z-direction given by z =ZS+(k-1)*(delta)z, for
                                  k
     k=1,2,...,N+1, where (delta)z=(ZF-ZS)/N is the panel width.
     Constraint: N >= 5.

16:  NBDCND -- INTEGER                                      Input
     On entry: specifies the type of boundary conditions at z =
     ZS and z = ZF.
     NBDCND = 0
           if the solution is periodic in z, i.e.,
           u(x,y,ZF)=u(x,y,ZS).

     NBDCND = 1
           if the solution is specified at z = ZS and z = ZF.

     NBDCND = 2
           if the solution is specified at z = ZS and the
           derivative of the solution with respect to z is
           specified at z = ZF.

     NBDCND = 3
           if the derivative of the solution with respect to z is
           specified at z = ZS and z = ZF.

     NBDCND = 4
           if the derivative of the solution with respect to z is
           specified at z = ZS and the solution is specified at z
           = ZF.
      Constraint: 0 <= NBDCND <= 4.

17:  BDZS(LDIMF,M+1) -- DOUBLE PRECISION array              Input
     On entry: the values of the derivative of the solution with
     respect to z at z = ZS. When NBDCND = 3 or 4, BDZS
     (i,j)=u (x ,y ,ZS)=u(x,y,z), for i=1,2,...,L+1;
            z  i  j
     j=1,2,...,M+1.

     When NBDCND has any other value, BDZS is not referenced.

18:  BDZF(LDIMF,M+1) -- DOUBLE PRECISION array              Input
     On entry: the values of the derivative of the solution with
     respect to z at z = ZF. When NBDCND = 2 or 3, BDZF
     (i,j)=u (x ,y ,ZF)=u(x,y,z), for i=1,2,...,L+1;
            z  i  j
     j=1,2,...,M+1.

     When NBDCND has any other value, BDZF is not referenced.

19:  LAMBDA -- DOUBLE PRECISION                             Input
     On entry: the constant (lambda) in the Helmholtz equation.
     For certain positive values of (lambda) a solution to the
     differential equation may not exist, and close to these
     values the solution of the discretized problem will be
     extremely ill-conditioned. If (lambda)>0, then D03FAF will
     set IFAIL to 3, but will still attempt to find a solution.
     However, since in general the values of (lambda) for which
     no solution exists cannot be predicted a priori, the user is
     advised to treat any results computed with (lambda)>0 with
     great caution.

20:  LDIMF -- INTEGER                                       Input
     On entry:
     the first dimension of the arrays F, BDYS, BDYF, BDZS and
     BDZF as declared in the (sub)program from which D03FAF is
     called.
     Constraint: LDIMF >= L + 1.

21:  MDIMF -- INTEGER                                       Input
     On entry: the second dimension of the array F and
     the first dimension of the arrays BDXS and BDXF as declared
     in the (sub)program from which D03FAF is called.
     Constraint: MDIMF >= M + 1.

22:  F(LDIMF,MDIMF,N+1) -- DOUBLE PRECISION array    Input/Output
     On entry: the values of the right-side of the Helmholtz
     equation and boundary values (if any).

     F(i,j,k)=f(x ,y ,z ) i=2,3,...,L, j=2,3,...,M and k
                 i  j  k
     =2,3,...,N.

     On the boundaries F is defined by
     LBDCND    F(1,j,k)  F(L+1,j,k)
```

```
0          f(XS,y ,z )f(XS,y ,z )
                 j  k      j  k

1          u(XS,y ,z )u(XF,y ,z )
                 j  k      j  k

2          u(XS,y ,z )f(XF,y ,z )  j=1,2,...,M+1
                 j  k      j  k

3          f(XS,y ,z )f(XF,y ,z )  k=1,2,...,N+1
                 j  k      j  k

Note: if the table calls for both the solution u and the
right-hand side f on a boundary, then the solution must be
specified. On exit: F contains the solution u(i,j,k) of the
finite difference approximation for the grid point (
x ,y ,z ) for i=1,2,...,L+1, j=1,2,...,M+1 and k=1,2,...,N+1.
 i  j  k

23:  PERTRB -- DOUBLE PRECISION                           Output
     On exit: PERTRB = 0, unless a solution to Poisson's
     equation ((lambda)=0) is required with a combination of
     periodic or derivative boundary conditions (LBDCND, MBDCND
     and NBDCND = 0 or 3). In this case a solution may not exist.
     PERTRB is a constant, calculated and subtracted from the
     array F, which ensures that a solution exists. D03FAF then
     computes this solution, which is a least-squares solution to
     the original approximation. This solution is not unique and
     is unnormalised. The value of PERTRB should be small
     compared to the right-hand side F, otherwise a solution has
     been obtained to an essentially different problem. This
     comparison should always be made to insure that a meaningful
     solution has been obtained.

24:  W(LWRK) -- DOUBLE PRECISION array                 Workspace

25:  LWRK -- INTEGER                                       Input
     On entry:
     the dimension of the array W as declared in the (sub)program
     from which D03FAF is called.
     LRWK>=2*(N+1)*max(L,M)+3*L+3*M+4*N+6 is an upper bound on
     the required size of W. If LWRK is too small, the routine
     exits with IFAIL = 2, and if on entry IFAIL = 0 or IFAIL = -
     1, a message is output giving the exact value of LWRK
     required to solve the current problem.

26:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. Users who are
     unfamiliar with this parameter should refer to the Essential
     Introduction for details.

     On exit: IFAIL = 0 unless the routine detects an error or
     gives a warning (see Section 6).

     For this routine, because the values of output parameters
     may be useful even if IFAIL /=0 on exit, users are
     recommended to set IFAIL to -1 before entry. It is then
     essential to test the value of IFAIL on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry XS >= XF,

     or       L < 5,

     or       LBDCND < 0,

     or       LBDCND > 4,

     or       YS >= YF,

     or       M < 5,

     or       MBDCND < 0,

     or       MBDCND > 4,

     or       ZS >= ZF,

     or       N < 5,

     or       NBDCND < 0,

     or       NBDCND > 4,

     or       LDIMF < L + 1 > 0,

     or       MDIMF < M + 1.

IFAIL= 2
     On entry LWRK is too small.

IFAIL= 3
     On entry (lambda) > 0.

7. Accuracy

None.

8. Further Comments
```

```
          The execution time is roughly proportional to
          L*M*N*(log L+log M+5), but also depends on input parameters
                    2     2
          LBDCND and MBDCND.

          9. Example

          The example solves the Helmholz equation

                          2     2     2
                         dd u  dd u  dd u
                         ----+ ----+ ----+(lambda)u=f(x,y,z)
                           2     2     2
                         ddx   ddy   ddz

                                                (pi)
          for (x,y,z)is in [0,1]*[0,2(pi)]*[0, ----] where (lambda)=-2, and
                                                 2
          f(x,y,z) is derived from the exact solution

                                           4
                               u(x,y,z)=x sin(y)cos(z).

          The equation is subject to the following boundary conditions,
          again derived from the exact solution given above.

               u(0,y,z) and u(1,y,z) are prescribed (i.e., LBDCND = 1).

               u(x,0,z)=u(x,2(pi),z) (i.e., MBDCND = 0).

                                    (pi)
               u(x,y,0) and u (x,y, ----) are prescribed (i.e. NBDCND = 2).
                             x       2

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

     E01(3NAG)         Foundation Library (12/10/92)         E01(3NAG)

          E01 -- Interpolation                          Introduction -- E01
                                    Chapter E01
                                   Interpolation

          1. Scope of the Chapter

          This chapter is concerned with the interpolation of a function of
          one or two variables. When provided with the value of the
          function (and possibly one or more of its lowest-order
          derivatives) at each of a number of values of the variable(s),
          the routines provide either an interpolating function or an
          interpolated value. For some of the interpolating functions,
          there are supporting routines to evaluate, differentiate or
          integrate them.

          2. Background to the Problems

          In motivation and in some of its numerical processes, this
          chapter has much in common with Chapter E02 (Curve and Surface
          Fitting). For this reason, we shall adopt the same terminology
          and refer to dependent variable and independent variable(s)
          instead of function and variable(s). Where there is only one
          independent variable, we shall denote it by x and the dependent
          variable by y. Thus, in the basic problem considered in this
          chapter, we are given a set of distinct values x ,x ,...,x  of x
                                                          1  2      m
          and a corresponding set of values y ,y ,...,y  of y, and we shall
                                             1  2      m
          describe the problem as being one of interpolating the data
          points (x ,y ), rather than interpolating a function. In modern
                   r  r
          usage, however, interpolation can have either of two rather
```

different meanings, both relevant to routines in this chapter. They are

(a) the determination of a function of x which takes the value y_r at $x=x_r$, for r=1,2,...,m (an interpolating function or interpolant),

(b) the determination of the value (interpolated value or interpolate) of an interpolating function at any given value, say $\hat{x}$, of x within the range of the x_r (so as to estimate the value at $\hat{x}$ of the function underlying the data).

The latter is the older meaning, associated particularly with the use of mathematical tables. The term 'function underlying the data', like the other terminology described above, is used so as to cover situations additional to those in which the data points have been computed from a known function, as with a mathematical table. In some contexts, the function may be unknown, perhaps representing the dependency of one physical variable on another, say temperature upon time.

Whether the underlying function is known or unknown, the object of interpolation will usually be to approximate it to acceptable accuracy by a function which is easy to evaluate anywhere in some range of interest. Piecewise polynomials such as cubic splines (see Section 2.2 of the E02 Chapter Introduction for definitions of terms in this case), being easy to evaluate and also capable of approximating a wide variety of functions, are the types of function mostly used in this chapter as interpolating functions.

Piecewise polynomials also, to a large extent, avoid the well-known problem of large unwanted fluctuations which can arise when interpolating a data set with a simple polynomial. Fluctuations can still arise but much less frequently and much less severely than with simple polynomials. Unwanted fluctuations are avoided altogether by a routine using piecewise cubic polynomials having only first derivative continuity. It is designed especially for monotonic data, but for other data still provides an interpolant which increases, or decreases, over the same intervals as the data.

The concept of interpolation can be generalised in a number of ways. For example, we may be required to estimate the value of the underlying function at a value $\hat{x}$ outside the range of the data. This is the process of extrapolation. In general, it is a good deal less accurate than interpolation and is to be avoided whenever possible.

Interpolation can also be extended to the case of two independent variables. We shall denote these by x and y, and the dependent variable by f. Methods used depend markedly on whether or not the data values of f are given at the intersections of a rectangular mesh in the (x,y)-plane. If they are, bicubic splines (see Section 2.3.2 of the E02 Chapter Introduction) are very suitable and usually very effective for the problem. For other cases, perhaps where the f values are quite arbitrarily scattered in the (x,y)-plane, polynomials and splines are not at all appropriate and special forms of interpolating function have to be employed. Many such forms have been devised and two of the most successful are in routines in this chapter. They both have continuity in first, but not higher, derivatives.

3. Recommendations on Choice and Use of Routines

3.1. General

Before undertaking interpolation, in other than the simplest cases, the user should seriously consider the alternative of using a routine from Chapter E02 to approximate the data by a polynomial or spline containing significantly fewer coefficients than the corresponding interpolating function. This approach is much less liable to produce unwanted fluctuations and so can often provide a better approximation to the function underlying the data.

When interpolation is employed to approximate either an underlying function or its values, the user will need to be satisfied that the accuracy of approximation achieved is adequate. There may be a means for doing this which is particular to the application, or the routine used may itself provide a means. In other cases, one possibility is to repeat the interpolation using one or more extra data points, if they are available, or otherwise one or more fewer, and to compare the results. Other possibilities, if it is an interpolating function which is determined, are to examine the function graphically, if that gives sufficient accuracy, or to observe the behaviour of the differences in a finite-difference table, formed from evaluations of the interpolating function at equally-spaced values of x over the range of interest. The spacing should be small enough to cause the typical size of the differences to decrease as the order of difference increases.

3.2. One Independent Variable

E01BAF computes an interpolating cubic spline, using a particular choice for the set of knots which has proved generally satisfactory in practice. If the user wishes to choose a different set, a cubic spline routine from Chapter E02, namely E02BAF, may be used in its interpolating mode, setting NCAP7 = M+ 4 and all elements of the parameter W to unity. These routines provide the interpolating function in B-spline form (see Section 2.2.2 in the E02 Chapter Introduction). Routines for evaluating, differentiating and integrating this form are discussed in Section 3.7 of the E02 Chapter Introduction.

The cubic spline does not always avoid unwanted fluctuations, especially when the data show a steep slope close to a region of small slope, or when the data inadequately represent the underlying curve. In such cases, E01BEF can be very useful. It derives a piecewise cubic polynomial (with first derivative continuity) which, between any adjacent pair of data points, either increases all the way, or decreases all the way (or stays constant). It is especially suited to data which are monotonic over their whole range.

In this routine, the interpolating function is represented simply by its value and first derivative at the data points. Supporting routines compute its value and first derivative elsewhere, as well as its definite integral over an arbitary interval.

3.3. Two Independent Variables

3.3.1. Data on a rectangular mesh

Given the value f_{qr} of the dependent variable f at the point (x_q,y_r) in the plane of the independent variables x and y, for each q=1,2,...,m and r=1,2,...,n (so that the points (x_q,y_r) lie at the m*n intersections of a rectangular mesh), E01DAF computes an interpolating bicubic spline, using a particular choice for each of the spline's knot-set. This choice, the same as in E01BAF , has proved generally satisfactory in practice. If, instead, the user wishes to specify his own knots, a routine from Chapter E02, namely E02DAF, may be adapted (it is more cumbersome for the purpose, however, and much slower for larger problems). Using m and n in the above sense, the parameter M must be set to m*n, PX and PY must be set to m+4 and n+4 respectively and all elements of W should be set to unity. The recommended value for EPS is zero.

3.3.2. Arbitrary data

As remarked at the end of Section 2, special types of interpolating are required for this problem, which can often be difficult to solve satisfactorily. Two of the most successful are employed in E01SAF and E01SEF, the two routines which (with their respective evaluation routines E01SBF and E01SFF) are provided for the problem. Definitions can be found in the routine documents. Both interpolants have first derivative continuity and are 'local', in that their value at any point depends only on data in the immediate neighbourhood of the point. This latter feature is necessary for large sets of data to avoid prohibitive computing time.

The relative merits of the two methods vary with the data and it is not possible to predict which will be the better in any particular case.

E01BAF(3NAG) Foundation Library (12/10/92) E01BAF(3NAG)

E01 -- Interpolation E01BAF

E01BAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E01BAF determines a cubic spline interpolant to a given set of data.

2. Specification

```
       SUBROUTINE E01BAF (M, X, Y, LAMDA, C, LCK, WRK, LWRK,
      1                   IFAIL)
       INTEGER          M, LCK, LWRK, IFAIL
       DOUBLE PRECISION X(M), Y(M), LAMDA(LCK), C(LCK), WRK(LWRK)
```

3. Description

This routine determines a cubic spline $s(x)$, defined in the range $x_1 <= x <= x_m$, which interpolates (passes exactly through) the set of data points (x_i, y_i), for $i=1,2,...,m$, where $m>=4$ and $x_1 < x_2 < ... < x_m$ end conditions are not imposed. The spline interpolant chosen has $m-4$ interior knots $\lambda_5, \lambda_6, ..., \lambda_m$, which are set to the values of $x_3, x_4, ..., x_{m-2}$ respectively. This spline is represented in its B-spline form (see Cox [1]):

$$s(x) = \sum_{i=1}^{m} c_i N_i(x),$$

where $N_i(x)$ denotes the normalised B-Spline of degree 3, defined upon the knots (lambda) ,(lambda) ,...,(lambda) , and c

i i+1 i+4 i
denotes its coefficient, whose value is to be determined by the routine.

The use of B-splines requires eight additional knots $(lambda)_1$, $(lambda)_2$, $(lambda)_3$, $(lambda)_4$, $(lambda)_{m+1}$, $(lambda)_{m+2}$, $(lambda)_{m+3}$ and $(lambda)_{m+4}$ to be specified; the routine sets the first four of these to x_1 and the last four to x_m.

The algorithm for determining the coefficients is as described in [1] except that QR factorization is used instead of LU decomposition. The implementation of the algorithm involves setting up appropriate information for the related routine E02BAF followed by a call of that routine. (For further details of E02BAF, see the routine document.)

Values of the spline interpolant, or of its derivatives or definite integral, can subsequently be computed as detailed in Section 8.

5. Parameters

1: M -- INTEGER Input
On entry: m, the number of data points. Constraint: M >= 4.

2: X(M) -- DOUBLE PRECISION array Input
On entry: X(i) must be set to x_i, the ith data value of the independent variable x, for i=1,2,...,m. Constraint: X(i) < X(i+1), for i=1,2,...,M-1.

3: Y(M) -- DOUBLE PRECISION array Input
On entry: Y(i) must be set to y_i, the ith data value of the dependent variable y, for i=1,2,...,m.

4: LAMDA(LCK) -- DOUBLE PRECISION array Output

```
    On exit: the value of (lambda) , the ith knot, for
                                  i
    i=1,2,...,m+4.

 5:  C(LCK) -- DOUBLE PRECISION array                      Output
    On exit: the coefficient c  of the B-spline N (x), for
                              i                  i
    i=1,2,...,m. The remaining elements of the array are not
    used.

 6:  LCK -- INTEGER                                          Input
    On entry:
    the dimension of the arrays LAMDA and C as declared in the
    (sub)program from which E01BAF is called.
    Constraint: LCK >= M + 4.

 7:  WRK(LWRK) -- DOUBLE PRECISION array                 Workspace

 8:  LWRK -- INTEGER                                         Input
    On entry:
    the dimension of the array WRK as declared in the
    (sub)program from which E01BAF is called.
    Constraint: LWRK>=6*M+16.

 9:  IFAIL -- INTEGER                                 Input/Output
    On entry: IFAIL must be set to 0, -1 or 1. For users not
    familiar with this parameter (described in the Essential
    Introduction) the recommended value is 0.

    On exit: IFAIL = 0 unless the routine detects an error (see
    Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
    On entry M < 4,

    or       LCK<M+4,

    or       LWRK<6*M+16.

IFAIL= 2
    The X-values fail to satisfy the condition

    X(1) < X(2) < X(3) <... < X(M).

7. Accuracy
```

The rounding errors incurred are such that the computed spline is an exact interpolant for a slightly perturbed set of ordinates $y_i+(\delta)y_i$. The ratio of the root-mean-square value of the $(\delta)y_i$ to that of the y_i is no greater than a small multiple of the relative machine precision.

8. Further Comments

The time taken by the routine is approximately proportional to m.

All the x_i are used as knot positions except x_2 and x_{m-1}. This choice of knots (see Cox [2]) means that s(x) is composed of m-3 cubic arcs as follows. If m=4, there is just a single arc space spanning the whole interval x_1 to x_4. If m>=5, the first and last arcs span the intervals x_1 to x_3 and x_{m-2} to x_m respectively. Additionally if m>=6, the ith arc, for i=2,3,...,m-4 spans the interval x_{i+1} to x_{i+2}.

After the call

```
       CALL E01BAF (M, X, Y, LAMDA, C, LCK, WRK, LWRK, IFAIL)
```

the following operations may be carried out on the interpolant s(x).

The value of s(x) at x = XVAL can be provided in the real variable SVAL by the call

```
       CALL E02BBF (M+4, LAMDA, C, XVAL, SVAL, IFAIL)
```

The values of s(x) and its first three derivatives at x = XVAL can be provided in the real array SDIF of dimension 4, by the call

```
       CALL E02BCF (M+4, LAMDA, C, XVAL, LEFT, SDIF, IFAIL)
```

Here LEFT must specify whether the left- or right-hand value of the third derivative is required (see E02BCF for details).

The value of the integral of s(x) over the range x_1 to x_m can be provided in the real variable SINT by

```
       CALL E02BDF (M+4, LAMDA, C, SINT, IFAIL)
```

```
          9. Example

          The example program sets up data from 7 values of the exponential
          function in the interval 0 to 1. E01BAF is then called to compute
          a spline interpolant to these data.

          The spline is evaluated by E02BBF, at the data points and at
          points halfway between each adjacent pair of data points, and the
                                          x
          spline values and the values of e  are printed out.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

\begin{verbatim}

     E01BEF(3NAG)      Foundation Library (12/10/92)      E01BEF(3NAG)

          E01 -- Interpolation                                     E01BEF
                  E01BEF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          E01BEF computes a monotonicity-preserving piecewise cubic Hermite
```

interpolant to a set of data points.

2. Specification

```
      SUBROUTINE E01BEF (N, X, F, D, IFAIL)
      INTEGER          N, IFAIL
      DOUBLE PRECISION X(N), F(N), D(N)
```

3. Description

This routine estimates first derivatives at the set of data points (x_r, f_r), for r=1,2,...,n, which determine a piecewise cubic Hermite interpolant to the data, that preserves monotonicity over ranges where the data points are monotonic. If the data points are only piecewise monotonic, the interpolant will have an extremum at each point where monotonicity switches direction. The estimates of the derivatives are computed by a formula due to Brodlie, which is described in Fritsch and Butland [1], with suitable changes at the boundary points.

The routine is derived from routine PCHIM in Fritsch [2].

Values of the computed interpolant, and of its first derivative and definite integral, can subsequently be computed by calling E01BFF, E01BGF and E01BHF, as described in Section 8

4. References

[1] Fritsch F N and Butland J (1984) A Method for Constructing Local Monotone Piecewise Cubic Interpolants. SIAM J. Sci. Statist. Comput. 5 300--304.

[2] Fritsch F N (1982) PCHIP Final Specifications. Report UCID-30194. Lawrence Livermore National Laboratory.

5. Parameters

1: N -- INTEGER Input
On entry: n, the number of data points. Constraint: N >= 2.

2: X(N) -- DOUBLE PRECISION array Input
On entry: X(r) must be set to x_r, the rth value of the independent variable (abscissa), for r=1,2,...,n.
Constraint: X(r) < X(r+1).

3: F(N) -- DOUBLE PRECISION array Input
On entry: F(r) must be set to f_r, the rth value of the

```
     dependent variable (ordinate), for r=1,2,...,n.

 4:  D(N) -- DOUBLE PRECISION array                        Output
     On exit: estimates of derivatives at the data points. D(r)
     contains the derivative at X(r).

 5:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry N < 2.

IFAIL= 2
     The values of X(r), for r=1,2,...,N, are not in strictly
     increasing order.

7. Accuracy

The computational errors in the array D should be negligible in
most practical situations.

8. Further Comments

The time taken by the routine is approximately proportional to n.

The values of the computed interpolant at the points PX(i), for
i=1,2,...,M, may be obtained in the real array PF, of length at
least M, by the call:

        CALL E01BFF(N,X,F,D,M,PX,PF,IFAIL)

where N, X and F are the input parameters to E01BEF and D is the
output parameter from E01BEF.

The values of the computed interpolant at the points PX(i), for i
= 1,2,...,M, together with its first derivatives, may be obtained
in the real arrays PF and PD, both of length at least M, by the
```

```
          call:

                  CALL E01BGF(N,X,F,D,M,PX,PF,PD,IFAIL)

          where N, X, F and D are as described above.

          The value of the definite integral of the interpolant over the
          interval A to B can be obtained in the real variable PINT by the
          call:

                  CALL E01BHF(N,X,F,D,A,B,PINT,IFAIL)

          where N, X, F and D are as described above.

          9. Example

          This example program reads in a set of data points, calls E01BEF
          to compute a piecewise monotonic interpolant, and then calls
          E01BFF to evaluate the interpolant at equally spaced points.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

16.4.4 Piecewise cubic Hermite interpolant

— nage.ht —

```
\begin{page}{manpageXXe01bff}{NAG Documentation: e01bff}
\beginscroll
\begin{verbatim}

     E01BFF(3NAG)      Foundation Library (12/10/92)      E01BFF(3NAG)

          E01 -- Interpolation                                    E01BFF
                  E01BFF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E01BFF evaluates a piecewise cubic Hermite interpolant at a set of points.

2. Specification

```
       SUBROUTINE E01BFF (N, X, F, D, M, PX, PF, IFAIL)
       INTEGER          N, M, IFAIL
       DOUBLE PRECISION X(N), F(N), D(N), PX(M), PF(M)
```

3. Description

This routine evaluates a piecewise cubic Hermite interpolant, as computed by E01BEF, at the points PX(i), for i=1,2,...,m. If any point lies outside the interval from X(1) to X(N), a value is extrapolated from the nearest extreme cubic, and a warning is returned.

The routine is derived from routine PCHFE in Fritsch [1].

4. References

[1] Fritsch F N (1982) PCHIP Final Specifications. Report UCID-30194. Lawrence Livermore National Laboratory.

5. Parameters

```
 1:  N -- INTEGER                                         Input

 2:  X(N) -- DOUBLE PRECISION array                       Input

 3:  F(N) -- DOUBLE PRECISION array                       Input

 4:  D(N) -- DOUBLE PRECISION array                       Input
     On entry: N, X, F and D must be unchanged from the previous
     call of E01BEF.

 5:  M -- INTEGER                                         Input
     On entry: m, the number of points at which the interpolant
     is to be evaluated. Constraint: M >= 1.

 6:  PX(M) -- DOUBLE PRECISION array                      Input
     On entry: the m values of x at which the interpolant is to
     be evaluated.
 7:  PF(M) -- DOUBLE PRECISION array                      Output
     On exit: PF(i) contains the value of the interpolant
     evaluated at the point PX(i), for i=1,2,...,m.

 8:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry N < 2.

IFAIL= 2
     The values of X(r), for r = 1,2,...,N, are not in strictly
     increasing order.

IFAIL= 3
     On entry M < 1.

IFAIL= 4
     At least one of the points PX(i), for i = 1,2,...,M, lies
     outside the interval [X(1),X(N)], and extrapolation was
     performed at all such points. Values computed at such points
     may be very unreliable.

7. Accuracy

The computational errors in the array PF should be negligible in
most practical situations.

8. Further Comments

The time taken by the routine is approximately proportional to
the number of evaluation points, m. The evaluation will be most
efficient if the elements of PX are in non-decreasing order (or,
more generally, if they are grouped in increasing order of the
intervals [X(r-1),X(r)]). A single call of E01BFF with m>1 is
more efficient than several calls with m=1.
```

```
          9. Example

          This example program reads in values of N, X, F and D, and then
          calls E01BFF to evaluate the interpolant at equally spaced
          points.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

                  E01BGF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          E01BGF evaluates a piecewise cubic Hermite interpolant and its
          first derivative at a set of points.

          2. Specification

                 SUBROUTINE E01BGF (N, X, F, D, M, PX, PF, PD, IFAIL)
                 INTEGER          N, M, IFAIL
```

```
      DOUBLE PRECISION X(N), F(N), D(N), PX(M), PF(M), PD(M)

3. Description

This routine evaluates a piecewise cubic Hermite interpolant, as
computed by E01BEF, at the points PX(i), for i=1,2,...,m. The
first derivatives at the points are also computed. If any point
lies outside the interval from X(1) to X(N), values of the
interpolant and its derivative are extrapolated from the nearest
extreme cubic, and a warning is returned.

If values of the interpolant only, and not of its derivative, are
required, E01BFF should be used.

The routine is derived from routine PCHFD in Fritsch [1].

4. References

                 E01BHF -- NAG Foundation Library Routine Document

         Note: Before using this routine, please read the Users' Note for
         your implementation to check implementation-dependent details.
         The symbol (*) after a NAG routine name denotes a routine that is
         not included in the Foundation Library.

         1. Purpose

         E01BHF evaluates the definite integral of a piecewise cubic
         Hermite interpolant over the interval [a,b].

         2. Specification

                SUBROUTINE E01BHF (N, X, F, D, A, B, PINT, IFAIL)
                INTEGER          N, IFAIL
                DOUBLE PRECISION X(N), F(N), D(N), A, B, PINT

         3. Description

         This routine evaluates the definite integral of a piecewise cubic
         Hermite interpolant, as computed by E01BEF, over the interval
```

[a,b].

If either a or b lies outside the interval from X(1) to X(N) computation of the integral involves extrapolation and a warning is returned.

The routine is derived from routine PCHIA in Fritsch [1].

4. References

[1] Fritsch F N (1982) PCHIP Final Specifications. Report UCID-30194. Lawrence Livermore National Laboratory .

5. Parameters

```
 1:  N -- INTEGER                                          Input

 2:  X(N) -- DOUBLE PRECISION array                        Input

 3:  F(N) -- DOUBLE PRECISION array                        Input

 4:  D(N) -- DOUBLE PRECISION array                        Input
     On entry: N, X, F and D must be unchanged from the previous
     call of E01BEF.

 5:  A -- DOUBLE PRECISION                                 Input

 6:  B -- DOUBLE PRECISION                                 Input
     On entry: the interval [a,b] over which integration is to
     be performed.

 7:  PINT -- DOUBLE PRECISION                             Output
     On exit: the value of the definite integral of the
     interpolant over the interval [a,b].

 8:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).
```

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

```
          IFAIL= 1
               On entry N < 2.

          IFAIL= 2
               The values of X(r), for r = 1,2,...,N, are not in strictly
               increasing order.

          IFAIL= 3
               On entry at least one of A or B lies outside the interval [X
               (1),X(N)], and extrapolation was performed to compute the
               integral. The value returned is therefore unreliable.

          7. Accuracy

          The computational error in the value returned for PINT should be
          negligible in most practical situations.

          8. Further Comments

          The time taken by the routine is approximately proportional to
          the number of data points included within the interval [a,b].

          9. Example

          This example program reads in values of N, X, F and D. It then
          reads in pairs of values for A and B, and evaluates the definite
          integral of the interpolant over the interval [A,B] until end-of-
          file is reached.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

E01DAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E01DAF computes a bicubic spline interpolating surface through a set of data values, given on a rectangular grid in the x-y plane.

2. Specification

```
       SUBROUTINE E01DAF (MX, MY, X, Y, F, PX, PY, LAMDA, MU, C,
      1                   WRK, IFAIL)
       INTEGER          MX, MY, PX, PY, IFAIL
       DOUBLE PRECISION X(MX), Y(MY), F(MX*MY), LAMDA(MX+4), MU(MX
      1                 +4), C(MX*MY), WRK((MX+6)*(MY+6))
```

3. Description

This routine determines a bicubic spline interpolant to the set of data points $(x_q,y_r,f_{q,r})$, for $q=1,2,...,m_x$; $r=1,2,...,m_y$. The spline is given in the B-spline representation

$$s(x,y)=\sum_{i=1}^{m_x}\sum_{j=1}^{m_y} c_{ij} M_i(x)N_j(y),$$

such that

$$s(x_q,y_r)=f_{q,r},$$

where $M_i(x)$ and $N_j(y)$ denote normalised cubic B-splines, the former defined on the knots $(lambda)_i$ to $(lambda)_{i+4}$ and the latter on the knots $(mu)_j$ to $(mu)_{j+4}$, and the c_{ij} are the spline coefficients. These knots, as well as the coefficients, are determined by the routine, which is derived from the routine B2IRE in Anthony et al[1]. The method used is described in Section 8.2.

For further information on splines, see Hayes and Halliday [4] for bicubic splines and de Boor [3] for normalised B-splines.

Values of the computed spline can subsequently be obtained by calling E02DEF or E02DFF as described in Section 8.3.

5. Parameters

1: MX -- INTEGER Input

2: MY -- INTEGER Input
On entry: MX and MY must specify m_x and m_y respectively, the number of points along the x and y axis that define the rectangular grid. Constraint: MX >= 4 and MY >= 4.

3: X(MX) -- DOUBLE PRECISION array Input

4: Y(MY) -- DOUBLE PRECISION array Input
On entry: X(q) and Y(r) must contain x_q, for $q=1,2,...,m_x$, and y_r, for $r=1,2,...,m_y$, respectively. Constraints:

X(q) < X(q+1), for $q=1,2,...,m_x-1$,

Y(r) < Y(r+1), for $r=1,2,...,m_y-1$.

y

5: F(MX*MY) -- DOUBLE PRECISION array Input
On entry: F(m_y*(q-1)+r) must contain $f_{q,r}$, for q=1,2,...,m_x; r=1,2,...,m_y.

6: PX -- INTEGER Output

7: PY -- INTEGER Output
On exit: PX and PY contain m_x+4 and m_y+4, the total number of knots of the computed spline with respect to the x and y variables, respectively.

8: LAMDA(MX+4) -- DOUBLE PRECISION array Output

9: MU(MY+4) -- DOUBLE PRECISION array Output
On exit: LAMDA contains the complete set of knots $(\lambda)_i$ associated with the x variable, i.e., the interior knots LAMDA(5), LAMDA(6), ..., LAMDA(PX-4), as well as the additional knots LAMDA(1) = LAMDA(2) = LAMDA(3) = LAMDA(4) = X(1) and LAMDA(PX-3) = LAMDA(PX-2) = LAMDA(PX-1) = LAMDA(PX) = X(MX) needed for the B-spline representation. MU contains the corresponding complete set of knots $(\mu)_i$ associated with the y variable.

10: C(MX*MY) -- DOUBLE PRECISION array Output
On exit: the coefficients of the spline interpolant. C(m_y*(i-1)+j) contains the coefficient c_{ij} described in Section 3.

11: WRK((MX+6)*(MY+6)) -- DOUBLE PRECISION array Workspace

12: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
: On entry MX < 4,

  or MY < 4.

IFAIL= 2
: On entry either the values in the X array or the values in the Y array are not in increasing order.

IFAIL= 3
: A system of linear equations defining the B-spline coefficients was singular; the problem is too ill-conditioned to permit solution.

7. Accuracy

The main sources of rounding errors are in steps (2), (3), (6) and (7) of the algorithm described in Section 8.2. It can be shown (Cox [2]) that the matrix A_x formed in step (2) has elements differing relatively from their true values by at most a small multiple of 3(epsilon), where (epsilon) is the machine precision. A_x is 'totally positive', and a linear system with such a coefficient matrix can be solved quite safely by elimination without pivoting. Similar comments apply to steps (6) and (7). Thus the complete process is numerically stable.

8. Further Comments

8.1. Timing

The time taken by this routine is approximately proportional to $m_x m_y$.

8.2. Outline of method used

The process of computing the spline consists of the following steps:

(1) choice of the interior x-knots $(lambda)_5$, $(lambda)_6$,..., $(lambda)_{m_x}$ as $(lambda)_i=x_{i-2}$, for $i=5,6,...,m_x$,

(2) formation of the system

$$A_x E=F,$$

where A_x is a band matrix of order m_x and bandwidth 4, containing in its qth row the values at x_q of the B-splines in x, F is the m_x by m_y rectangular matrix of values $f_{q,r}$, and E denotes an m_x by m_y rectangular matrix of intermediate coefficients,

(3) use of Gaussian elimination to reduce this system to band triangular form,

(4) solution of this triangular system for E,

(5) choice of the interior y knots $(mu)_5$, $(mu)_6$,...,$(mu)_{m_y}$ as $(mu)_i=y_{i-2}$, for i=5,6,...,m_y,

(6) formation of the system

$$A_y C^T=E^T,$$

where A_y is the counterpart of A_x for the y variable, and C denotes the m_x by m_y rectangular matrix of values of c_{ij},

(7) use of Gaussian elimination to reduce this system to band triangular form,

(8) solution of this triangular system for C^T and hence C.

For computational convenience, steps (2) and (3), and likewise steps (6) and (7), are combined so that the formation of A_x and A_y and the reductions to triangular form are carried out one row at a time.

8.3. Evaluation of Computed Spline

The values of the computed spline at the points (TX(r),TY(r)), for r = 1,2,...,N, may be obtained in the double precision array

FF, of length at least N, by the following call:

```
      IFAIL = 0
      CALL E02DEF(N,PX,PY,TX,TY,LAMDA,MU,C,FF,WRK,IWRK,IFAIL)
```

where PX, PY, LAMDA, MU and C are the output parameters of E01DAF , WRK is a double precision workspace array of length at least PY-4, and IWRK is an integer workspace array of length at least PY-4.

To evaluate the computed spline on an NX by NY rectangular grid of points in the x-y plane, which is defined by the x co-ordinates stored in TX(q), for q = 1,2,...,NX, and the y co-ordinates stored in TY(r), for r = 1,2,...,NY, returning the results in the double precision array FG which is of length at least NX*NY, the following call may be used:

```
       IFAIL = 0
       CALL E02DFF(NX,NY,PX,PY,TX,TY,LAMDA,MU,C,FG,WRK,LWRK,
      *            IWRK,LIWRK,IFAIL)
```

where PX, PY, LAMDA, MU and C are the output parameters of E01DAF , WRK is a double precision workspace array of length at least LWRK = min(NWRK1,NWRK2), NWRK1 = NX*4+PX, NWRK2 = NY*4+PY, and IWRK is an integer workspace array of length at least LIWRK = NY + PY - 4 if NWRK1 > NWRK2, or NX + PX - 4 otherwise. The result of the spline evaluated at grid point (q,r) is returned in element (NY*(q-1)+r) of the array FG.

9. Example

This program reads in values of m_x, x_q for q=1,2,...,m_x, m_y and y_r for r=1,2,...,m_y, followed by values of the ordinates $f_{q,r}$ defined at the grid points (x_q,y_r). It then calls E01DAF to compute a bicubic spline interpolant of the data values, and prints the values of the knots and B-spline coefficients. Finally it evaluates the spline at a small sample of points on a rectangular grid.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

     E01SAF(3NAG)      Foundation Library (12/10/92)      E01SAF(3NAG)

          E01 -- Interpolation                                      E01SAF
                  E01SAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          E01SAF generates a two-dimensional surface interpolating a set of
          scattered data points, using the method of Renka and Cline.

          2. Specification

                 SUBROUTINE E01SAF (M, X, Y, F, TRIANG, GRADS, IFAIL)
                 INTEGER          M, TRIANG(7*M), IFAIL
                 DOUBLE PRECISION X(M), Y(M), F(M), GRADS(2,M)

          3. Description

          This routine constructs an interpolating surface F(x,y) through a
          set of m scattered data points (x ,y ,f ), for r=1,2,...,m, using
                                          r  r  r
          a method due to Renka and Cline. In the (x,y) plane, the data
          points must be distinct. The constructed surface is continuous
          and has continuous first derivatives.

          The method involves firstly creating a triangulation with all the
```

(x,y) data points as nodes, the triangulation being as nearly equiangular as possible (see Cline and Renka [1]). Then gradients in the x- and y-directions are estimated at node r, for r=1,2,...,m, as the partial derivatives of a quadratic function of x and y which interpolates the data value f_r, and which fits the data values at nearby nodes (those within a certain distance chosen by the algorithm) in a weighted least-squares sense. The weights are chosen such that closer nodes have more influence than more distant nodes on derivative estimates at node r. The computed partial derivatives, with the f_r values, at the three nodes of each triangle define a piecewise polynomial surface of a certain form which is the interpolant on that triangle. See Renka and Cline [4] for more detailed information on the algorithm, a development of that by Lawson [2]. The code is derived from Renka [3].

The interpolant F(x,y) can subsequently be evaluated at any point (x,y) inside or outside the domain of the data by a call to E01SBF. Points outside the domain are evaluated by extrapolation.

5. Parameters

```
 1:  M -- INTEGER                                           Input
     On entry: m, the number of data points. Constraint: M >= 3.

 2:  X(M) -- DOUBLE PRECISION array                         Input

 3:  Y(M) -- DOUBLE PRECISION array                         Input
 4:  F(M) -- DOUBLE PRECISION array                         Input
     On entry: the co-ordinates of the rth data point, for
     r=1,2,...,m. The data points are accepted in any order, but
     see Section 8. Constraint: The (x,y) nodes must not all be
     collinear, and each node must be unique.

 5:  TRIANG(7*M) -- INTEGER array                          Output
     On exit: a data structure defining the computed
     triangulation, in a form suitable for passing to E01SBF.

 6:  GRADS(2,M) -- DOUBLE PRECISION array                  Output
     On exit: the estimated partial derivatives at the nodes, in
     a form suitable for passing to E01SBF. The derivatives at
     node r with respect to x and y are contained in GRADS(1,r)
     and GRADS(2,r) respectively, for r=1,2,...,m.

 7:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry M < 3.

IFAIL= 2
     On entry all the (X,Y) pairs are collinear.

IFAIL= 3
     On entry (X(i),Y(i)) = (X(j),Y(j)) for some i/=j.

7. Accuracy

On successful exit, the computational errors should be negligible
in most situations but the user should always check the computed
surface for acceptability, by drawing contours for instance. The
surface always interpolates the input data exactly.

8. Further Comments

The time taken for a call of E01SAF is approximately proportional
```

```
        to the number of data points, m. The routine is more efficient
        if, before entry, the values in X, Y, F are arranged so that the
        X array is in ascending order.

        9. Example

        This program reads in a set of 30 data points and calls E01SAF to
        construct an interpolating surface. It then calls E01SBF to
        evaluate the interpolant at a sample of points on a rectangular
        grid.

        Note that this example is not typical of a realistic problem: the
        number of data points would normally be larger, and the
        interpolant would need to be evaluated on a finer grid to obtain
        an accurate plot, say.

        The example program is not reproduced here. The source code for
        all example programs is distributed with the NAG Foundation
        Library software and should be available on-line.

        Note: Before using this routine, please read the Users' Note for
        your implementation to check implementation-dependent details.
        The symbol (*) after a NAG routine name denotes a routine that is
        not included in the Foundation Library.
```

1. Purpose

E01SBF evaluates at a given point the two-dimensional interpolant function computed by E01SAF.

2. Specification

```
       SUBROUTINE E01SBF (M, X, Y, F, TRIANG, GRADS, PX, PY, PF,
      1                   IFAIL)
       INTEGER          M, TRIANG(7*M), IFAIL
       DOUBLE PRECISION X(M), Y(M), F(M), GRADS(2,M), PX, PY, PF
```

3. Description

This routine takes as input the parameters defining the interpolant F(x,y) of a set of scattered data points (x_r,y_r,f_r), for r=1,2,...,m, as computed by E01SAF, and evaluates the interpolant at the point (px,py).

If (px,py) is equal to (x_r,y_r) for some value of r, the returned value will be equal to f_r.

If (px,py) is not equal to (x_r,y_r) for any r, the derivatives in GRADS will be used to compute the interpolant. A triangle is sought which contains the point (px,py), and the vertices of the triangle along with the partial derivatives and f_r values at the vertices are used to compute the value F(px,py). If the point (px,py) lies outside the triangulation defined by the input parameters, the returned value is obtained by extrapolation. In this case, the interpolating function F is extended linearly beyond the triangulation boundary. The method is described in more detail in Renka and Cline [2] and the code is derived from Renka [1].

E01SBF must only be called after a call to E01SAF.

4. References

```
     Interpolation Method. Rocky Mountain J. Math. 14 223--237.

5. Parameters

 1:  M -- INTEGER                                           Input

 2:  X(M) -- DOUBLE PRECISION array                         Input

 3:  Y(M) -- DOUBLE PRECISION array                         Input

 4:  F(M) -- DOUBLE PRECISION array                         Input

 5:  TRIANG(7*M) -- INTEGER array                           Input

 6:  GRADS(2,M) -- DOUBLE PRECISION array                   Input
     On entry: M, X, Y, F, TRIANG and GRADS must be unchanged
     from the previous call of E01SAF.

 7:  PX -- DOUBLE PRECISION                                 Input

 8:  PY -- DOUBLE PRECISION                                 Input
     On entry: the point (px,py) at which the interpolant is to
     be evaluated.

 9:  PF -- DOUBLE PRECISION                                Output
     On exit: the value of the interpolant evaluated at the
     point (px,py).

10:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry M < 3.

IFAIL= 2
     On entry the triangulation information held in the array
     TRIANG does not specify a valid triangulation of the data
     points. TRIANG may have been corrupted since the call to
```

```
          E01SAF.

     IFAIL= 3
          The evaluation point (PX,PY) lies outside the nodal
          triangulation, and the value returned in PF is computed by
          extrapolation.

     7. Accuracy

     Computational errors should be negligible in most practical
     situations.

     8. Further Comments

     The time taken for a call of E01SBF is approximately proportional
     to the number of data points, m.

     The results returned by this routine are particularly suitable
     for applications such as graph plotting, producing a smooth
     surface from a number of scattered points.

     9. Example

     See the example for E01SAF.

     The example program is not reproduced here. The source code for
     all example programs is distributed with the NAG Foundation
     Library software and should be available on-line.

```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E01SEF generates a two-dimensional surface interpolating a set of scattered data points, using a modified Shepard method.

2. Specification

```
       SUBROUTINE E01SEF (M, X, Y, F, RNW, RNQ, NW, NQ, FNODES,
      1                   MINNQ, WRK, IFAIL)
       INTEGER          M, NW, NQ, MINNQ, IFAIL
       DOUBLE PRECISION X(M), Y(M), F(M), RNW, RNQ, FNODES(5*M),
      1                 WRK(6*M)
```

3. Description

This routine constructs an interpolating surface F(x,y) through a set of m scattered data points (x_r,y_r,f_r), for r=1,2,...,m, using a modification of Shepard's method. The surface is continuous and has continuous first derivatives.

The basic Shepard method, described in [2], interpolates the input data with the weighted mean

$$F(x,y)=\frac{\sum_{r=1}^{m} w_r(x,y)f_r}{\sum_{r=1}^{m} w_r(x,y)},$$

where $w_r(x,y)=\frac{1}{d_r^2}$ and $d_r^2=(x-x_r)^2+(y-y_r)^2$.

r

The basic method is global in that the interpolated value at any point depends on all the data, but this routine uses a modification due to Franke and Nielson described in [1], whereby the method becomes local by adjusting each $w_r(x,y)$ to be zero outside a circle with centre (x_r,y_r) and some radius R_w. Also, to improve the performance of the basic method, each f_r above is replaced by a function $f_r(x,y)$, which is a quadratic fitted by weighted least-squares to data local to (x_r,y_r) and forced to interpolate (x_r,y_r,f_r). In this context, a point (x,y) is defined to be local to another point if it lies within some distance R_q of it. Computation of these quadratics constitutes the main work done by this routine. If there are less than 5 other points within distance R_q from (x_r,y_r), the quadratic is replaced by a linear function. In cases of rank-deficiency, the minimum norm solution is computed.

The user may specify values for R_w and R_q, but it is usually easier to choose instead two integers N_w and N_q, from which the routine will compute R_w and R_q. These integers can be thought of as the average numbers of data points lying within distances R_w and R_q respectively from each node. Default values are provided, and advice on alternatives is given in Section 8.2.

The interpolant F(x,y) generated by this routine can subsequently be evaluated for any point (x,y) in the domain of the data by a call to E01SFF.

```
     Brandon/Systems Press Inc., Princeton. 517--523.

 5. Parameters

  1:  M -- INTEGER                                          Input
      On entry: m, the number of data points. Constraint: M >= 3.

  2:  X(M) -- DOUBLE PRECISION array                        Input

  3:  Y(M) -- DOUBLE PRECISION array                        Input

  4:  F(M) -- DOUBLE PRECISION array                        Input
      On entry: the co-ordinates of the rth data point, for
      r=1,2,...,m. The order of the data points is immaterial.
      Constraint: each of the (X(r),Y(r)) pairs must be unique.

  5:  RNW -- DOUBLE PRECISION                        Input/Output

  6:  RNQ -- DOUBLE PRECISION                        Input/Output
      On entry: suitable values for the radii R  and R ,
                                               w      q
      described in Section 3. Constraint: RNQ <= 0 or 0 < RNW <=
      RNQ. On exit: if RNQ is set less than or equal to zero on
      entry, then default values for both of them will be computed
      from the parameters NW and NQ, and RNW and RNQ will contain
      these values on exit.

  7:  NW -- INTEGER                                         Input

  8:  NQ -- INTEGER                                         Input
      On entry: if RNQ > 0.0 and RNW > 0.0 then NW and NQ are not
      referenced by the routine. Otherwise, NW and NQ must specify
      suitable values for the integers N  and N  described in
                                        w      q
      Section 3.

      If NQ is less than or equal to zero on entry, then default
      values for both of them, namely NW = 9 and NQ = 18, will be
      used. Constraint: NQ <= 0 or 0 < NW <= NQ.

  9:  FNODES(5*M) -- DOUBLE PRECISION array                Output
      On exit: the coefficients of the constructed quadratic
      nodal functions. These are in a form suitable for passing to
      E01SFF.

 10:  MINNQ -- INTEGER                                     Output
      On exit: the minimum number of data points that lie within
      radius RNQ of any node, and thus define a nodal function. If
      MINNQ is very small (say, less than 5), then the interpolant
      may be unsatisfactory in regions where the data points are
      sparse.

 11:  WRK(6*M) -- DOUBLE PRECISION array                 Workspace

 12:  IFAIL -- INTEGER                                Input/Output
      On entry: IFAIL must be set to 0, -1 or 1. For users not
      familiar with this parameter (described in the Essential
      Introduction) the recommended value is 0.

      On exit: IFAIL = 0 unless the routine detects an error (see
      Section 6).
```

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

```
IFAIL= 1
     On entry M < 3.

IFAIL= 2
     On entry RNQ > 0 and either RNW > RNQ or RNW <= 0.

IFAIL= 3
     On entry NQ > 0 and either NW > NQ or NW <= 0.

IFAIL= 4
     On entry (X(i),Y(i)) is equal to (X(j),Y(j)) for some i/=j.
```

7. Accuracy

On successful exit, the computational errors should be negligible in most situations but the user should always check the computed surface for acceptability, by drawing contours for instance. The surface always interpolates the input data exactly.

8. Further Comments

8.1. Timing

The time taken for a call of E01SEF is approximately proportional to the number of data points, m, provided that N_q is of the same order as its default value (18). However if N_q is increased so that the method becomes more global, the time taken becomes approximately proportional to m^2.

```
                  m N} {{\rm w}}$ and ${\rm N} {{\rm q}}$
          8.2. Choice of ${\
          Note first that the radii R  and R , described in Section 3, are
                                     w      q

                            / N            / N
                       D   /   w      D   /   q
          computed as  -  /    -- and  -  /    -- respectively, where D is
                       2\/    m       2/    m
          the maximum distance between any pair of data points.
          Default values N =9 and N =18 work quite well when the data
                          w       q
          points are fairly uniformly distributed. However, for data having
          some regions with relatively few points or for small data sets
          (m<25), a larger value of N  may be needed. This is to ensure a
                                    w
          reasonable number of data points within a distance R  of each
                                                             w
          node, and to avoid some regions in the data area being left
          outside all the discs of radius R  on which the weights w (x,y)
                                          w                      r
          are non-zero. Maintaining N  approximately equal to 2N  is
                                     q                          w
          usually an advantage.

          Note however that increasing N  and N  does not improve the
                                        w     q
          quality of the interpolant in all cases. It does increase the
          computational cost and makes the method less local.

          9. Example

          This program reads in a set of 30 data points and calls E01SEF to
          construct an interpolating surface. It then calls E01SFF to
          evaluate the interpolant at a sample of points on a rectangular
          grid.

          Note that this example is not typical of a realistic problem: the
          number of data points would normally be larger, and the
          interpolant would need to be evaluated on a finer grid to obtain
          an accurate plot, say.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

     E01SFF(3NAG)      Foundation Library (12/10/92)      E01SFF(3NAG)

          E01 -- Interpolation                                       E01SFF
                  E01SFF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          E01SFF evaluates at a given point the two-dimensional
          interpolating function computed by E01SEF.

          2. Specification

                 SUBROUTINE E01SFF (M, X, Y, F, RNW, FNODES, PX, PY, PF,
                1                   IFAIL)
                 INTEGER          M, IFAIL
                 DOUBLE PRECISION X(M), Y(M), F(M), RNW, FNODES(5*M), PX,
                1                 PY, PF

          3. Description

          This routine takes as input the interpolant F(x,y) of a set of
          scattered data points (x ,y ,f ), for r=1,2,...,m, as computed by
                                  r  r  r
          E01SEF, and evaluates the interpolant at the point (px,py).

          If (px,py) is equal to (x ,y ) for some value of r, the returned
                                   r  r
```

```
value will be equal to f .
                        r

If (px,py) is not equal to (x ,y ) for any r, all points that are
                             r  r
within distance RNW of (px,py), along with the corresponding
nodal functions given by FNODES, will be used to compute a value
of the interpolant.

E01SFF must only be called after a call to E01SEF.

5. Parameters

 1:  M -- INTEGER                                           Input

 2:  X(M) -- DOUBLE PRECISION array                         Input

 3:  Y(M) -- DOUBLE PRECISION array                         Input

 4:  F(M) -- DOUBLE PRECISION array                         Input

 5:  RNW -- DOUBLE PRECISION                                Input

 6:  FNODES(5*M) -- DOUBLE PRECISION array                  Input
     On entry: M, X, Y, F, RNW and FNODES must be unchanged from
     the previous call of E01SEF.

 7:  PX -- DOUBLE PRECISION                                 Input

 8:  PY -- DOUBLE PRECISION                                 Input
     On entry: the point (px,py) at which the interpolant is to
     be evaluated.

 9:  PF -- DOUBLE PRECISION                                Output
     On exit: the value of the interpolant evaluated at the
     point (px,py).

10:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
                 Introduction) the recommended value is 0.

                 On exit: IFAIL = 0 unless the routine detects an error (see
                 Section 6).

            6. Error Indicators and Warnings

            Errors detected by the routine:

            If on entry IFAIL = 0 or -1, explanatory error messages are
            output on the current error message unit (as defined by X04AAF).

            IFAIL= 1
                 On entry M < 3.

            IFAIL= 2
                 The interpolant cannot be evaluated because the evaluation
                 point (PX,PY) lies outside the support region of the data
                 supplied in X, Y and F. This error exit will occur if
                 (PX,PY) lies at a distance greater than or equal to RNW from
                 every point given by arrays X and Y.

                 The value 0.0 is returned in PF. This value will not provide
                 continuity with values obtained at other points (PX,PY),
                 i.e., values obtained when IFAIL = 0 on exit.

            7. Accuracy

            Computational errors should be negligible in most practical
            situations.

            8. Further Comments

            The time taken for a call of E01SFF is approximately proportional
            to the number of data points, m.

            The results returned by this routine are particularly suitable
            for applications such as graph plotting, producing a smooth
            surface from a number of scattered points.

            9. Example

            See the example for E01SEF.

            The example program is not reproduced here. The source code for
            all example programs is distributed with the NAG Foundation
            Library software and should be available on-line.

3.8. Index

1. Scope of the Chapter

The main aim of this chapter is to assist the user in finding a function which approximates a set of data points. Typically the data contain random errors, as of experimental measurement, which need to be smoothed out. To seek an approximation to the data, it is first necessary to specify for the approximating function a mathematical form (a polynomial, for example) which contains a number of unspecified coefficients: the appropriate fitting routine then derives for the coefficients the values which provide the best fit of that particular form. The chapter deals mainly with curve and surface fitting (i.e., fitting with functions of one and of two variables) when a polynomial or a cubic spline is used as the fitting function, since these cover the most common needs. However, fitting with other functions and/or more variables can be undertaken by means of general linear or nonlinear routines (some of which are contained in other chapters) depending on whether the coefficients in the function occur linearly or nonlinearly. Cases where a graph rather than a set of data points is given can be treated simply by first reading a suitable set of points from the graph.

The chapter also contains routines for evaluating, differentiating and integrating polynomial and spline curves and surfaces, once the numerical values of their coefficients have been determined.

2. Background to the Problems

2.1. Preliminary Considerations

In the curve-fitting problems considered in this chapter, we have a dependent variable y and an independent variable x, and we are given a set of data points (x_r,y_r), for r=1,2,...,m. The preliminary matters to be considered in this section will, for simplicity, be discussed in this context of curve-fitting problems. In fact, however, these considerations apply equally well to surface and higher-dimensional problems. Indeed, the discussion presented carries over essentially as it stands if, for these cases, we interpret x as a vector of several independent variables and correspondingly each x_r as a vector containing the rth data value of each independent variable.

We wish, then, to approximate the set of data points as closely as possible with a specified function, f(x) say, which is as smooth as possible -- f(x) may, for example, be a polynomial. The requirements of smoothness and closeness conflict, however, and a balance has to be struck between them. Most often, the smoothness requirement is met simply by limiting the number of coefficients allowed in the fitting function -- for example, by restricting the degree in the case of a polynomial. Given a particular number of coefficients in the function in question, the fitting routines of this chapter determine the values of the coefficients such that the 'distance' of the function from the data points is as small as possible. The necessary balance is struck by the user comparing a selection of such fits having different numbers of coefficients. If the number of coefficients is too low, the approximation to the data will be poor. If the number is too high, the fit will be too close to the data, essentially following the random errors and tending to have unwanted fluctuations between the data points. Between these extremes, there is often a group of fits all similarly close to the data points and then, particularly when least-squares polynomials are used, the choice is clear: it is the fit from this group having the smallest number of coefficients.

The above process can be seen as the user minimizing the smoothness measure (i.e., the number of coefficients) subject to the distance from the data points being acceptably small. Some of the routines, however, do this task themselves. They use a different measure of smoothness (in each case one that is continuous) and minimize it subject to the distance being less than a threshold specified by the user. This is a much more automatic process, requiring only some experimentation with the threshold.

2.1.1. Fitting criteria: norms

A measure of the above 'distance' between the set of data points and the function f(x) is needed. The distance from a single data point (x_r, y_r) to the function can simply be taken as

$$\epsilon_r = y_r - f(x_r), \qquad (1)$$

and is called the residual of the point. (With this definition, the residual is regarded as a function of the coefficients contained in f(x); however, the term is also used to mean the particular value of ϵ_r which corresponds to the fitted values of the coefficients.) However, we need a measure of distance for the set of data points as a whole. Three different measures are used in the different routines (which measure to select, according to circumstances, is discussed later in this sub-section). With ϵ_r defined in (1), these measures, or norms, are

$$\sum_{r=1}^{m} |\epsilon_r|, \qquad (2)$$

$$\sqrt{\sum_{r=1}^{m} (\epsilon)_r^2}, \text{ and} \qquad (3)$$

$$\max_r |(\epsilon)_r|, \qquad (4)$$

respectively the l_1 norm, the l_2 norm and the l_∞ norm.

Minimization of one or other of these norms usually provides the fitting criterion, the minimization being carried out with respect to the coefficients in the mathematical form used for f(x): with respect to the b_i for example if the mathematical form is the power series in (8) below. The fit which results from minimizing (2) is known as the l_1 fit, or the fit in the l_1 norm: that which results from minimizing (3) is the l_2 fit, the well-known least-squares fit (minimizing (3) is equivalent to minimizing the square of (3), i.e., the sum of squares of residuals, and it is the latter which is used in practice), and that from minimizing (4) is the l_∞, or minimax, fit.

Strictly speaking, implicit in the use of the above norms are the statistical assumptions that the random errors in the y_r are independent of one another and that any errors in the x_r are negligible by comparison. From this point of view, the use of the l_2 norm is appropriate when the random errors in the y_r have a normal distribution, and the l_∞ norm is appropriate when they have a rectangular distribution, as when fitting a table of values rounded to a fixed number of decimal places. The l_1 norm is appropriate when the error distribution has its frequency function proportional to the negative exponential of the modulus of the normalised error -- not a common situation.

However, the user is often indifferent to these statistical considerations, and simply seeks a fit which he can assess by inspection, perhaps visually from a graph of the results. In this event, the l_1 norm is particularly appropriate when the data are thought to contain some 'wild' points (since fitting in this norm tends to be unaffected by the presence of a small number of such points), though of course in simple situations the user may prefer to identify and reject these points. The l_∞ norm should be used only when the maximum residual is of particular concern, as may be the case for example when the data values have been obtained by accurate computation, as of a mathematical function. Generally, however, a routine based on least-squares should be preferred, as being computationally faster and usually providing more information on which to assess the results. In many problems the three fits will not differ significantly for practical purposes.

Some of the routines based on the l_2 norm do not minimize the norm itself but instead minimize some (intuitively acceptable) measure of smoothness subject to the norm being less than a user-specified threshold. These routines fit with cubic or bicubic splines (see (10) and (14) below) and the smoothing measures relate to the size of the discontinuities in their third derivatives. A much more automatic fitting procedure follows from this approach.

2.1.2. Weighting of data points

The use of the above norms also assumes that the data values y_r are of equal (absolute) accuracy. Some of the routines enable an allowance to be made to take account of differing accuracies. The allowance takes the form of 'weights' applied to the y-values so that those values known to be more accurate have a greater influence on the fit than others. These weights, to be supplied by the user, should be calculated from estimates of the absolute accuracies of the y-values, these estimates being expressed as standard deviations, probable errors or some other measure which has the same dimensions as y. Specifically, for each y_r the corresponding weight w_r should be inversely proportional to the accuracy estimate of y_r. For example, if the percentage accuracy is the same for all y_r, then the absolute accuracy of y_r is proportional to y_r (assuming y_r to be positive, as it usually is in such cases) and so $w_r=K/y_r$, for r=1,2,...,m, for an arbitrary positive constant K. (This definition of weight is stressed because often weight is defined as the square of that used here.) The norms (2), (3) and (4) above are then replaced respectively by

$$\sum_{r=1}^{m} |w_r \epsilon_r|, \tag{5}$$

$$\sqrt{\sum_{r=1}^{m} w_r^2 \epsilon_r^2}, \quad \text{and} \tag{6}$$

$$\max_r |w_r \epsilon_r|. \tag{7}$$

Again it is the square of (6) which is used in practice rather than (6) itself.

2.2. Curve Fitting

When, as is commonly the case, the mathematical form of the fitting function is immaterial to the problem, polynomials and cubic splines are to be preferred because their simplicity and ease of handling confer substantial benefits. The cubic spline is the more versatile of the two. It consists of a number of cubic polynomial segments joined end to end with continuity in first and second derivatives at the joins. The third derivative at the joins is in general discontinuous. The x-values of the joins are called knots, or, more precisely, interior knots. Their number determines the number of coefficients in the spline, just as the degree determines the number of coefficients in a polynomial.

2.2.1. Representation of polynomials

Rather than using the power-series form

$$f(x)==b_0+b_1x+b_2x^2+...+b_kx^k \tag{8}$$

to represent a polynomial, the routines in this chapter use the Chebyshev series form

$$f(x) = \frac{1}{2}a_0T_0(x)+a_1T_1(x)+a_2T_2(x)+\ldots+a_kT_k(x), \qquad (9)$$

where $T_i(x)$ is the Chebyshev polynomial of the first kind of degree i (see Cox and Hayes [1], page 9), and where the range of x has been normalised to run from -1 to +1. The use of either form leads theoretically to the same fitted polynomial, but in practice results may differ substantially because of the effects of rounding error. The Chebyshev form is to be preferred, since it leads to much better accuracy in general, both in the computation of the coefficients and in the subsequent evaluation of the fitted polynomial at specified points. This form also has other advantages: for example, since the later terms in (9) generally decrease much more rapidly from left to right than do those in (8), the situation is more often encountered where the last terms are negligible and it is obvious that the degree of the polynomial can be reduced (note that on the interval $-1\le x\le 1$ for all i, $T_i(x)$ attains the value unity but never exceeds it, so that the coefficient a_i gives directly the maximum value of the term containing it).

2.2.2. Representation of cubic splines

A cubic spline is represented in the form

$$f(x) = c_1N_1(x)+c_2N_2(x)+\ldots+c_pN_p(x), \qquad (10)$$

where $N_i(x)$, for i=1,2,...,p, is a normalised cubic B-spline (see Hayes [2]). This form, also, has advantages of computational speed and accuracy over alternative representations.

2.3. Surface Fitting

There are now two independent variables, and we shall denote these by x and y. The dependent variable, which was denoted by y in the curve-fitting case, will now be denoted by f. (This is a rather different notation from that indicated for the general-dimensional problem in the first paragraph of Section 2.1 , but it has some advantages in presentation.)

Again, in the absence of contrary indications in the particular application being considered, polynomials and splines are the approximating functions most commonly used. Only splines are used by the surface-fitting routines in this chapter.

2.3.1. Bicubic splines: definition and representation

The bicubic spline is defined over a rectangle R in the (x,y) plane, the sides of R being parallel to the x- and y-axes. R is divided into rectangular panels, again by lines parallel to the axes. Over each panel the bicubic spline is a bicubic polynomial, that is it takes the form

$$\sum_{i=0}^{3} \sum_{j=0}^{3} a_{ij} x^i y^j . \qquad (13)$$

Each of these polynomials joins the polynomials in adjacent panels with continuity up to the second derivative. The constant x-values of the dividing lines parallel to the y-axis form the set of interior knots for the variable x, corresponding precisely to the set of interior knots of a cubic spline. Similarly, the constant y-values of dividing lines parallel to the x-axis form the set of interior knots for the variable y. Instead of representing the bicubic spline in terms of the above set of bicubic polynomials, however, it is represented, for the sake of computational speed and accuracy, in the form

$$f(x,y)= \sum_{i=1}^{p} \sum_{j=1}^{q} c_{ij} M_i(x)N_j(y), \qquad (14)$$

where $M_i(x)$, for i=1,2,...,p, and $N_j(y)$, for j=1,2,...,q, are normalised B-splines (see Hayes and Halliday [4] for further details of bicubic splines and Hayes [2] for normalised B-splines).

2.4. General Linear and Nonlinear Fitting Functions

We have indicated earlier that, unless the data-fitting application under consideration specifically requires some other type of fitting function, a polynomial or a spline is usually to be preferred. Special routines for these functions, in one and in two variables, are provided in this chapter. When the application does specify some other fitting function, however, it may be treated by a routine which deals with a general linear function, or by one for a general nonlinear function, depending on whether the coefficients in the given function occur linearly or nonlinearly.

The general linear fitting function can be written in the form

$$f(x)==c_1 (phi)_1 (x)+c_2 (phi)_2 (x)+...+c_p (phi)_p (x), \qquad (15)$$

where x is a vector of one or more independent variables, and the $(phi)_i$ are any given functions of these variables (though they must be linearly independent of one another if there is to be the possibility of a unique solution to the fitting problem). This is not intended to imply that each $(phi)_i$ is necessarily a function of all the variables: we may have, for example, that each $(phi)_i$ is a function of a different single variable, and even that one of the $(phi)_i$ is a constant. All that is required is that a value of each $(phi)_i (x)$ can be computed when a value of each independent variable is given.

When the fitting function f(x) is not linear in its coefficients, no more specific representation is available in general than f(x) itself. However, we shall find it helpful later on to indicate the fact that f(x) contains a number of coefficients (to be determined by the fitting process) by using instead the notation f(x;c), where c denotes the vector of coefficients. An example of a nonlinear fitting function is

$$f(x;c)==c_1 +c_2 exp(-c_4 x)+c_3 exp(-c_5 x), \qquad (16)$$

which is in one variable and contains five coefficients. Note that here, as elsewhere in this Chapter Introduction, we use the term 'coefficients' to include all the quantities whose values are to be determined by the fitting process, not just those which occur linearly. We may observe that it is only the presence of the coefficients c_4 and c_5 which makes the form (16) nonlinear. If the values of these two coefficients were known beforehand, (16) would instead be a linear function which, in terms of the general linear form (15), has p=3 and

$$(phi)_1 (x)==1, \quad (phi)_2 (x)==exp(-c_4 x), \text{ and } (phi)_3 (x)==exp(-c_5 x).$$

We may note also that polynomials and splines, such as (9) and (14), are themselves linear in their coefficients. Thus if, when fitting with these functions, a suitable special routine is not available (as when more than two independent variables are involved or when fitting in the l_1 norm), it is appropriate to use a routine designed for a general linear function.

2.5. Constrained Problems

So far, we have considered only fitting processes in which the values of the coefficients in the fitting function are determined by an unconstrained minimization of a particular norm. Some fitting problems, however, require that further restrictions be placed on the determination of the coefficient values. Sometimes these restrictions are contained explicitly in the formulation of the problem in the form of equalities or inequalities which the coefficients, or some function of them, must satisfy. For example, if the fitting function contains a term Aexp(-kx), it may be required that k>=0. Often, however, the equality or inequality constraints relate to the value of the fitting function or its derivatives at specified values of the independent variable(s), but these too can be expressed in terms of the coefficients of the fitting function, and it is appropriate to do this if a general linear or nonlinear routine is being used. For example, if the fitting function is that given in (10), the requirement that the first derivative of the function at $x=x_0$ be non-negative can be expressed as

$$c_1N_1'(x_0)+c_2N_2'(x_0)+...+c_pN_p'(x_0)>=0, \qquad (17)$$

where the prime denotes differentiation with respect to x and each derivative is evaluated at $x=x_0$. On the other hand, if the requirement had been that the derivative at $x=x_0$ be exactly zero, the inequality sign in (17) would be replaced by an equality.

Routines which provide a facility for minimizing the appropriate norm subject to such constraints are discussed in Section 3.6.

3. Recommendations on Choice and Use of Routines

3.1. General

The choice of a routine to treat a particular fitting problem will depend first of all on the fitting function and the norm to be used. Unless there is good reason to the contrary, the fitting function should be a polynomial or a cubic spline (in the appropriate number of variables) and the norm should be the l_2 norm (leading to the least-squares fit). If some other function is to be used, the choice of routine will depend on whether the function is nonlinear (in which case see Section 3.5.2) or linear in its coefficients (see Section 3.5.1), and, in the latter case, on whether the l_1 or l_2 norm is to be used. The latter section is appropriate for polynomials and splines, too, if the l_1 norm is preferred.

In the case of a polynomial or cubic spline, if there is only one independent variable, the user should choose a spline (Section 3.3) when the curve represented by the data is of complicated form, perhaps with several peaks and troughs. When the curve is of simple form, first try a polynomial (see Section 3.2) of low degree, say up to degree 5 or 6, and then a spline if the polynomial fails to provide a satisfactory fit. (Of course, if third-derivative discontinuities are unacceptable to the user, a polynomial is the only choice.) If the problem is one of surface fitting, one of the spline routines should be used (Section 3.4). If the problem has more than two independent variables, it may be treated by the general linear routine in Section 3.5.1, again using a polynomial in the first instance.

Another factor which affects the choice of routine is the presence of constraints, as previously discussed in Section 2.5. Indeed this factor is likely to be overriding at present, because of the limited number of routines which have the necessary facility. See Section 3.6.

3.1.1. Data considerations

A satisfactory fit cannot be expected by any means if the number and arrangement of the data points do not adequately represent the character of the underlying relationship: sharp changes in behaviour, in particular, such as sharp peaks, should be well covered. Data points should extend over the whole range of interest of the independent variable(s): extrapolation outside the data ranges is most unwise. Then, with polynomials, it is advantageous to have additional points near the ends of the ranges, to counteract the tendency of polynomials to develop fluctuations in these regions. When, with polynomial curves, the user can precisely choose the x-values of the data, the special points defined in Section 3.2.2 should be selected. With splines the choice is less critical as long as the character of the relationship is adequately represented. All fits should be tested graphically before accepting them as satisfactory.

For this purpose it should be noted that it is not sufficient to plot the values of the fitted function only at the data values of the independent variable(s); at the least, its values at a similar number of intermediate points should also be plotted, as unwanted fluctuations may otherwise go undetected. Such fluctuations are the less likely to occur the lower the number of coefficients chosen in the fitting function. No firm guide can be given, but as a rough rule, at least initially, the number of coefficients should not exceed half the number of data points (points with equal or nearly equal values of the independent variable, or both independent variables in surface fitting, counting as a single point for this purpose). However, the situation may be such, particularly with a small number of data points, that a satisfactorily close fit to the data cannot be achieved without unwanted fluctuations occurring. In such cases, it is often possible to improve the situation by a transformation of one or more of the variables, as discussed in the next paragraph: otherwise it will be necessary to provide extra data points. Further advice on curve fitting is given in Cox and Hayes [1] and, for polynomials only, in Hayes [3] of Section 2.7. Much of the advice applies also to surface fitting; see also the Routine Documents.

3.1.2. Transformation of variables

Before starting the fitting, consideration should be given to the choice of a good form in which to deal with each of the variables: often it will be satisfactory to use the variables as they stand, but sometimes the use of the logarithm, square root, or some other function of a variable will lead to a better-behaved relationship. This question is customarily taken into account in preparing graphs and tables of a relationship and the same considerations apply when curve or surface fitting. The practical context will often give a guide. In general, it is best to avoid having to deal with a relationship whose behaviour in one region is radically different from that in another. A steep rise at the left-hand end of a curve, for example, can often best be treated by curve fitting in terms of log(x+c) with some suitable value of the constant c. A case when such a transformation gave substantial benefit is discussed in Hayes [3] page 60. According to the features exhibited in any particular case, transformation of either dependent variable or independent variable(s) or both may be beneficial. When there is a choice it is usually better to transform the independent variable(s): if the dependent variable is transformed, the weights attached to the data points must be adjusted. Thus (denoting the dependent variable by y, as in the notation for curves) if the y_r to be fitted have been obtained by a transformation y=g(Y) from original data values Y_r, with weights W_r, for r=1,2,...,m, we must take

$$w_r=W_r/(dy/dY), \qquad (18)$$

where the derivative is evaluated at Y_r. Strictly, the transformation of Y and the adjustment of weights are valid only when the data errors in the Y_r are small compared with the range spanned by the Y_r, but this is usually the case.

3.2. Polynomial Curves

3.2.1. Least-squares polynomials: arbitrary data points

E02ADF fits to arbitrary data points, with arbitrary weights, polynomials of all degrees up to a maximum degree k, which is at choice. If the user is seeking only a low degree polynomial, up to degree 5 or 6 say, k=10 is an appropriate value, providing there are about 20 data points or more. To assist in deciding the degree of polynomial which satisfactorily fits the data, the routine provides the root-mean-square-residual s_i for all degrees i=1,2,...,k. In a satisfactory case, these s_i will decrease steadily as i increases and then settle down to a fairly constant value, as shown in the example

i	s_i
0	3.5215
1	0.7708
2	0.1861
3	0.0820
4	0.0554
5	0.0251
6	0.0264
7	0.0280
8	0.0277
9	0.0297
10	0.0271

If the s_i values settle down in this way, it indicates that the closest polynomial approximation justified by the data has been achieved. The degree which first gives the approximately constant value of s_i (degree 5 in the example) is the appropriate degree to select. (Users who are prepared to accept a fit higher than sixth degree, should simply find a high enough value of k to enable the type of behaviour indicated by the example to be detected: thus they should seek values of k for which at least 4 or 5 consecutive values of s_i are approximately the same.) If the degree were allowed to go high enough, s_i would, in most cases, eventually start to decrease again, indicating that the data points are being fitted too closely and that undesirable fluctuations are developing between the points. In some cases, particularly with a small number of data points, this final decrease is not distinguishable from the initial decrease in s_i. In such cases, users may seek an acceptable fit by examining the graphs of several of the polynomials obtained. Failing this, they may (a) seek a transformation of variables which improves the behaviour, (b) try fitting a spline, or (c) provide more data points. If data can be provided simply by drawing an approximating curve by hand and reading points from it, use the points discussed in Section 3.2.2.

3.2.2. Least-squares polynomials: selected data points

When users are at liberty to choose the x-values of data points, such as when the points are taken from a graph, it is most advantageous when fitting with polynomials to use the values x_r =cos((pi)r/n), for r=0,1,...,n for some value of n, a suitable value for which is discussed at the end of this section. Note that these x_r relate to the variable x after it has been normalised so that its range of interest is -1 to +1. E02ADF may then be used as in Section 3.2.1 to seek a satisfactory fit.

3.3. Cubic Spline Curves

3.3.1. Least-squares cubic splines

E02BAF fits to arbitrary data points, with arbitrary weights, a cubic spline with interior knots specified by the user. The choice of these knots so as to give an acceptable fit must largely be a matter of trial and error, though with a little experience a satisfactory choice can often be made after one or two trials. It is usually best to start with a small number of knots (too many will result in unwanted fluctuations in the fit, or even in there being no unique solution) and, examining the fit graphically at each stage, to add a few knots at a time at places where the fit is particularly poor. Moving the existing knots towards these places will also often improve the fit. In regions where the behaviour of the curve underlying the data is changing rapidly, closer knots will be needed than elsewhere. Otherwise, positioning is not usually very critical and equally-spaced knots are often satisfactory. See also the next section, however.

A useful feature of the routine is that it can be used in applications which require the continuity to be less than the normal continuity of the cubic spline. For example, the fit may be required to have a discontinuous slope at some point in the range. This can be achieved by placing three coincident knots at the given point. Similarly a discontinuity in the second derivative at a point can be achieved by placing two knots there. Analogy with these discontinuous cases can provide guidance in more usual cases: for example, just as three coincident knots can produce a discontinuity in slope, so three close knots can produce a rapid change in slope. The closer the knots are, the more rapid can the change be.

Figure 1

Please see figure in printed Reference Manual

An example set of data is given in Figure 1. It is a rather tricky set, because of the scarcity of data on the right, but it will serve to illustrate some of the above points and to show some of the dangers to be avoided. Three interior knots (indicated by the vertical lines at the top of the diagram) are chosen as a start. We see that the resulting curve is not steep enough in the middle and fluctuates at both ends, severely on the right. The spline is unable to cope with the shape and more knots are needed.

In Figure 2, three knots have been added in the centre, where the data shows a rapid change in behaviour, and one further out at each end, where the fit is poor. The fit is still poor, so a further knot is added in this region and, in Figure 3, disaster ensues in rather spectacular fashion.

Figure 2
Please see figure in printed Reference Manual

Figure 3
Please see figure in printed Reference Manual

The reason is that, at the right-hand end, the fits in Figure 1 and Figure 2 have been interpreted as poor simply because of the fluctuations about the curve underlying the data (or what it is naturally assumed to be). But the fitting process knows only about the data and nothing else about the underlying curve, so it is important to consider only closeness to the data when deciding goodness of fit.

Thus, in Figure 1, the curve fits the last two data points quite well compared with the fit elsewhere, so no knot should have been added in this region. In Figure 2, the curve goes exactly through the last two points, so a further knot is certainly not needed here.

Figure 4
Please see figure in printed Reference Manual

Figure 4 shows what can be achieved without the extra knot on each of the flat regions. Remembering that within each knot interval the spline is a cubic polynomial, there is really no need to have more than one knot interval covering each flat region.

What we have, in fact, in Figure 2 and Figure 3 is a case of too many knots (so too many coefficients in the spline equation) for the number of data points. The warning in the second paragraph of Section 2.1 was that the fit will then be too close to the data, tending to have unwanted fluctuations between the data points. The warning applies locally for splines, in the sense that, in localities where there are plenty of data points, there can be a lot of knots, as long as there are few knots where there are few points, especially near the ends of the interval. In the present example, with so few data points on the right, just the one extra knot in Figure 2 is too many! The signs are clearly present, with the last two points fitted exactly (at least to the graphical accuracy and actually much closer than that) and fluctuations within the last two knot-intervals (cf. Figure 1, where only the final point is fitted exactly and one of the wobbles spans several data points).

The situation in Figure 3 is different. The fit, if computed exactly, would still pass through the last two data points, with even more violent fluctuations. However, the problem has become so ill-conditioned that all accuracy has been lost. Indeed, if the last interior knot were moved a tiny amount to the right, there would be no unique solution and an error message would have been caused. Near-singularity is, sadly, not picked up by the routine, but can be spotted readily in a graph, as Figure 3. B-spline coefficients becoming large, with alternating signs, is another indication. However, it is better to avoid such situations, firstly by providing, whenever possible, data adequately covering the range of interest, and secondly by placing knots only where there is a reasonable amount of data.

The example here could, in fact, have utilised from the start the observation made in the second paragraph of this section, that three close knots can produce a rapid change in slope. The example has two such rapid changes and so requires two sets of three close knots (in fact, the two sets can be so close that one knot can serve in both sets, so only five knots prove sufficient in Figure 4). It should be noted, however, that the rapid turn occurs within the range spanned by the three knots. This is the reason that the six knots in Figure 2 are not satisfactory as they do not quite span the two turns.

Some more examples to illustrate the choice of knots are given in Cox and Hayes [1].

3.3.2. Automatic fitting with cubic splines

E02BEF also fits cubic splines to arbitrary data points with arbitrary weights but itself chooses the number and positions of the knots. The user has to supply only a threshold for the sum of squares of residuals. The routine first builds up a knot set by a series of trial fits in the l norm. Then, with the knot set

2
decided, the final spline is computed to minimize a certain smoothing measure subject to satisfaction of the chosen threshold. Thus it is easier to use than E02BAF (see previous section), requiring only some experimentation with this threshold. It should therefore be first choice unless the user has a preference for the ordinary least-squares fit or, for example, wishes to experiment with knot positions, trying to keep their number down (E02BEF aims only to be reasonably frugal with knots).

3.4. Spline Surfaces

3.4.1. Least-squares bicubic splines

E02DAF fits to arbitrary data points, with arbitrary weights, a bicubic spline with its two sets of interior knots specified by the user. For choosing these knots, the advice given for cubic splines, in Section 3.3.1 above, applies here too. (See also the next section, however.) If changes in the behaviour of the surface underlying the data are more marked in the direction of one variable than of the other, more knots will be needed for the former variable than the latter. Note also that, in the surface case, the reduction in continuity caused by coincident knots will extend across the whole spline surface: for example, if three knots associated with the variable x are chosen to coincide at a value L, the spline surface will have a discontinuous slope across the whole extent of the line x=L.

With some sets of data and some choices of knots, the least-squares bicubic spline will not be unique. This will not occur, with a reasonable choice of knots, if the rectangle R is well covered with data points: here R is defined as the smallest rectangle in the (x,y) plane, with sides parallel to the axes, which contains all the data points. Where the least-squares solution is not unique, the minimal least-squares solution is computed, namely that least-squares solution which has the smallest value of the sum of squares of the B-spline coefficients c_{ij} (see the end of Section 2.3.2 above). This choice of least-squares solution tends to minimize the risk of unwanted fluctuations in the fit. The fit will not be reliable, however, in regions where there are few or no data points.

3.4.2. Automatic fitting with bicubic splines

E02DDF also fits bicubic splines to arbitrary data points with arbitrary weights but chooses the knot sets itself. The user has to supply only a threshold for the sum of squares of residuals. Just like the automatic curve E02BEF (Section 3.3.2), E02DDF then builds up the knot sets and finally fits a spline minimizing a smoothing measure subject to satisfaction of the threshold. Again, this easier to use routine is normally to be preferred, at least in the first instance.

E02DCF is a very similar routine to E02DDF but deals with data points of equal weight which lie on a rectangular mesh in the (x,y) plane. This kind of data allows a very much faster computation and so is to be preferred when applicable. Substantial departures from equal weighting can be ignored if the user is not concerned with statistical questions, though the quality of the fit will suffer if this is taken too far. In such cases, the user should revert to E02DDF.

3.5. General Linear and Nonlinear Fitting Functions

3.5.1. General linear functions

For the general linear function (15), routines are available for fitting in the l_1 and l_2 norms. The least-squares routines (which are to be preferred unless there is good reason to use another norm -- see Section 2.1.1) are in Chapter F04. The l_1 routine is E02GAF.

All the above routines are essentially linear algebra routines, and in considering their use we need to view the fitting process in a slightly different way from hitherto. Taking y to be the dependent variable and x the vector of independent variables, we have, as for equation (1) but with each x_r now a vector,

$$\epsilon_r = y_r - f(x_r) \quad r=1,2,...,m.$$

Substituting for f(x) the general linear form (15), we can write this as

$$c_1\phi_1(x_r)+c_2\phi_2(x_r)+...+c_p\phi_p(x_r)=y_r-\epsilon_r, \quad r=1,2,...,m \qquad (19)$$

Thus we have a system of linear equations in the coefficients c_j. Usually, in writing these equations, the ϵ_r are omitted and simply taken as implied. The system of equations is then described as an overdetermined system (since we must have m>=p if there is to be the possibility of a unique solution to our fitting problem), and the fitting process of computing the c_j to minimize one or other of the norms (2), (3) and (4) can be described, in relation to the system of equations, as solving the overdetermined system in that particular norm. In matrix notation, the system can be written as

$$(Phi)c=y, \qquad (20)$$

where (Phi) is the m by p matrix whose element in row r and column j is $(phi)_j(x_r)$, for r=1,2,...,m; j=1,2,...,p. The vectors c and y respectively contain the coefficients c_j and the data values y_r.

The routines, however, use the standard notation of linear algebra, the overdetermined system of equations being denoted by

$$Ax=b \qquad (21)$$

The correspondence between this notation and that which we have used for the data-fitting problem (equation (20)) is therefore given by

$$A==(Phi), \quad x==c \quad b==y \qquad (22)$$

Note that the norms used by these routines are the unweighted norms (2) and (3). If the user wishes to apply weights to the data points, that is to use the norms (5) or (6), the equivalences (22) should be replaced by

$$A==D(Phi), \quad x==c \quad b==Dy$$

where D is a diagonal matrix with w_r as the rth diagonal element. Here w_r, for r=1,2,...,m, is the weight of the rth data point as defined in Section 2.1.2.

3.5.2. Nonlinear functions

Routines for fitting with a nonlinear function in the l_2 norm are provided in Chapter E04, and that chapter's Introduction should be consulted for the appropriate choice of routine. Again, however, the notation adopted is different from that we have used for data fitting. In the latter, we denote the fitting function by f(x;c), where x is the vector of independent variables and c is the vector of coefficients, whose values are to be determined. The squared l_2 norm, to be minimized with respect to the elements of c, is then

$$\sum_{r=1}^{m} w_r^2 [y_r - f(x_r;c)]^2 \qquad (23)$$

where y_r is the rth data value of the dependent variable, x_r is the vector containing the rth values of the independent variables, and w_r is the corresponding weight as defined in Section 2.1.2.

On the other hand, in the nonlinear least-squares routines of Chapter E04, the function to be minimized is denoted by

$$\sum_{i=1}^{m} f_i^2(x), \qquad (24)$$

the minimization being carried out with respect to the elements of the vector x. The correspondence between the two notations is given by

$x \equiv c$ and

$f_i(x) \equiv w_r[y_r - f(x_r;c)], \quad i=r=1,2,...,m.$

Note especially that the vector x of variables of the nonlinear least-squares routines is the vector c of coefficients of the data-fitting problem, and in particular that, if the selected routine requires derivatives of the $f_i(x)$ to be provided, these are derivatives of $w_r[y_r - f(x_r;c)]$ with respect to the coefficients of the data-fitting problem.

3.6. Constraints

At present, there are only a limited number of routines which fit subject to constraints. Chapter E04 contains a routine, E04UCF, which can be used for fitting with a nonlinear function in the l_2 norm subject to equality or inequality constraints. This routine, unlike those in that chapter suited to the unconstrained case, is not designed specifically for minimizing functions which are sums of squares, and so the function (23) has to be treated as a general nonlinear function. The E04 Chapter Introduction should be consulted.

The remaining constraint routine relates to fitting with polynomials in the l_2 norm. E02AGF deals with polynomial curves and allows precise values of the fitting function and (if required) all its derivatives up to a given order to be prescribed at one or more values of the independent variable.

3.7. Evaluation, Differentiation and Integration

Routines are available to evaluate, differentiate and integrate polynomials in Chebyshev-series form and cubic or bicubic splines in B-spline form. These polynomials and splines may have been produced by the various fitting routines or, in the case of polynomials, from prior calls of the differentiation and integration routines themselves.

E02AEF and E02AKF evaluate polynomial curves: the latter has a longer parameter list but does not require the user to normalise the values of the independent variable and can accept coefficients which are not stored in contiguous locations. E02BBF evaluates cubic spline curves, and E02DEF and E02DFF bicubic spline surfaces.

Differentiation and integration of polynomial curves are carried out by E02AHF and E02AJF respectively. The results are provided in Chebyshev-series form and so repeated differentiation and integration are catered for. Values of the derivative or integral can then be computed using the appropriate evaluation routine.

For splines the differentiation and integration routines provided are of a different nature from those for polynomials. E02BCF provides values of a cubic spline curve and its first three derivatives (the rest, of course, are zero) at a given value of x spline over its whole range. These routines can also be applied to surfaces of the form (14). For example, if, for each value of j in turn, the coefficients c_{ij}, for i=1,2,...,p are supplied to E02BCF with $x=x_0$ and on each occasion we select from the output the value of the second derivative, d_j say, and if the whole set of d_j are then supplied to the same routine with $x=y_0$, the output will contain all the values at (x_0,y_0) of

$$\frac{\partial^2 f}{\partial x^2} \quad \text{and} \quad \frac{\partial^{r+2} f}{\partial x^2 \partial y^r}, \quad r=1,2,3.$$

Equally, if after each of the first p calls of E02BCF we had selected the function value (E02BBF would also provide this) instead of the second derivative and we had supplied these values to E02BDF, the result obtained would have been the value of

$$\int_A^B f(x_0,y)dy,$$

where A and B are the end-points of the y interval over which the spline was defined.

      1                 (2*KPLUS1), A(NROWS,KPLUS1), S(KPLUS1)
```

3. Description

This routine determines least-squares polynomial approximations of degrees 0,1,...,k to the set of data points (x_r,y_r) with weights w_r, for r=1,2,...,m.

The approximation of degree i has the property that it minimizes $(\sigma)_i$ the sum of squares of the weighted residuals $(\epsilon)_r$, where

$$(\epsilon)_r=w_r(y_r-f_r)$$

and f_r is the value of the polynomial of degree i at the rth data point.

Each polynomial is represented in Chebyshev-series form with

normalised argument x. This argument lies in the range -1 to +1 and is related to the original variable x by the linear transformation

$$x=\frac{(2x-x_{max}-x_{min})}{(x_{max}-x_{min})}.$$

Here x_{max} and x_{min} are respectively the largest and smallest values of x_r. The polynomial approximation of degree i is represented as

$$\frac{1}{2}a_{i+1,1}T_0(x)+a_{i+1,2}T_1(x)+a_{i+1,3}T_2(x)+...+a_{i+1,i+1}T_i(x),$$

where T (x) is the Chebyshev polynomial of the first kind of

$_j$

degree j with argument (x).

For i=0,1,...,k, the routine produces the values of $a_{i+1,j+1}$, for j=0,1,...,i, together with the value of the root mean square residual $s_i = \sqrt{\frac{(\sigma)_i}{m-i-1}}$. In the case m=i+1 the routine sets the value of s_i to zero.

The method employed is due to Forsythe [4] and is based upon the generation of a set of polynomials orthogonal with respect to summation over the normalised data set. The extensions due to Clenshaw [1] to represent these polynomials as well as the approximating polynomials in their Chebyshev-series forms are incorporated. The modifications suggested by Reinsch and Gentleman (see [5]) to the method originally employed by Clenshaw for evaluating the orthogonal polynomials from their Chebyshev-series representations are used to give greater numerical stability.

For further details of the algorithm and its use see Cox [2] and [3].

Subsequent evaluation of the Chebyshev-series representations of the polynomial approximations should be carried out using E02AEF.

5. Parameters

```
 1:  M -- INTEGER                                          Input
     On entry: the number m of data points. Constraint: M >=
     MDIST >= 2, where MDIST is the number of distinct x values
     in the data.

 2:  KPLUS1 -- INTEGER                                     Input
     On entry: k+1, where k is the maximum degree required.
     Constraint: 0 < KPLUS1 <= MDIST, where MDIST is the number
     of distinct x values in the data.

 3:  NROWS -- INTEGER                                      Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which E02ADF is called.
     Constraint: NROWS >= KPLUS1.

 4:  X(M) -- DOUBLE PRECISION array                        Input
     On entry: the values x  of the independent variable, for
                           r
     r=1,2,...,m. Constraint: the values must be supplied in non-
     decreasing order with X(M) > X(1).

 5:  Y(M) -- DOUBLE PRECISION array                        Input
     On entry: the values y  of the dependent variable, for
                           r
     r=1,2,...,m.

 6:  W(M) -- DOUBLE PRECISION array                        Input
     On entry: the set of weights, w , for r=1,2,...,m. For
                                    r
     advice on the choice of weights, see Section 2.1.2 of the
     Chapter Introduction. Constraint: W(r) > 0.0, for r=1,2,...m.

 7:  WORK1(3*M) -- DOUBLE PRECISION array              Workspace

 8:  WORK2(2*KPLUS1) -- DOUBLE PRECISION array         Workspace

 9:  A(NROWS,KPLUS1) -- DOUBLE PRECISION array            Output
```

On exit: the coefficients of $T_j(x)$ in the approximating polynomial of degree i. A(i+1,j+1) contains the coefficient $a_{i+1,j+1}$, for i=0,1,...,k; j=0,1,...,i.

10: S(KPLUS1) -- DOUBLE PRECISION array Output
On exit: S(i+1) contains the root mean square residual s_i, for i=0,1,...,k, as described in Section 3. For the interpretation of the values of the s_i and their use in selecting an appropriate degree, see Section 3.1 of the Chapter Introduction.

11: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
The weights are not all strictly positive.

IFAIL= 2
The values of X(r), for r=1,2,...,M are not in non-decreasing order.

IFAIL= 3
All X(r) have the same value: thus the normalisation of X is not possible.

IFAIL= 4
On entry KPLUS1 < 1 (so the maximum degree required is negative)

or KPLUS1 > MDIST, where MDIST is the number of distinct x values in the data (so there cannot be a unique solution for degree k=KPLUS1-1).

IFAIL= 5
NROWS < KPLUS1.

```
          7. Accuracy

          No error analysis for the method has been published. Practical
          experience with the method, however, is generally extremely
          satisfactory.

          8. Further Comments

          The time taken by the routine is approximately proportional to
          m(k+1)(k+11).

          The approximating polynomials may exhibit undesirable
          oscillations (particularly near the ends of the range) if the
          maximum degree k exceeds a critical value which depends on the
          number of data points m and their relative positions. As a rough
          guide, for equally-spaced data, this critical value is about

          2*\/m. For further details see Hayes [6] page 60.

          9. Example

          Determine weighted least-squares polynomial approximations of
          degrees 0, 1, 2 and 3 to a set of 11 prescribed data points. For
          the approximation of degree 3, tabulate the data and the
          corresponding values of the approximating polynomial, together
          with the residual errors, and also the values of the
          approximating polynomial at points half-way between each pair of
          adjacent data points.

          The example program supplied is written in a general form that
          will enable polynomial approximations of degrees 0,1,...,k to be
          obtained to m data points, with arbitrary positive weights, and
          the approximation of degree k to be tabulated. E02AEF is used to
          evaluate the approximating polynomial. The program is self-
          starting in that any number of data sets can be supplied.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

          E02 -- Curve and Surface Fitting                           E02AEF
                  E02AEF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          E02AEF evaluates a polynomial from its Chebyshev-series
          representation.

          2. Specification

                 SUBROUTINE E02AEF (NPLUS1, A, XCAP, P, IFAIL)
                 INTEGER          NPLUS1, IFAIL
                 DOUBLE PRECISION A(NPLUS1), XCAP, P

          3. Description

          This routine evaluates the polynomial

                        1
                        -a T (x)+a T (x)+a T (x)+...+a   T (x)
                        2 1 0     2 1     3 2        n+1 n

          for any value of x satisfying -1<=x<=1. Here T (x) denotes the
                                                        j
          Chebyshev polynomial of the first kind of degree j with argument

          x. The value of n is prescribed by the user.
```

In practice, the variable x will usually have been obtained from an original variable x, where $x_{min}<=x<=x_{max}$ and

$$x=\frac{((x-x_{min})-(x_{max}-x))}{(x_{max}-x_{min})}$$

Note that this form of the transformation should be used computationally rather than the mathematical equivalent

$$x=\frac{(2x-x_{min}-x_{max})}{(x_{max}-x_{min})}$$

since the former guarantees that the computed value of x differs from its true value by at most 4(epsilon), where (epsilon) is the machine precision, whereas the latter has no such guarantee.

The method employed is based upon the three-term recurrence relation due to Clenshaw [1], with modifications to give greater numerical stability due to Reinsch and Gentleman (see [4]).

For further details of the algorithm and its use see Cox [2] and [3].

4. References

[4] Gentlemen W M (1969) An Error Analysis of Goertzel's (Watt's) Method for Computing Fourier Coefficients. Comput.

J. 12 160--165.

5. Parameters

1: NPLUS1 -- INTEGER Input
On entry: the number n+1 of terms in the series (i.e., one greater than the degree of the polynomial). Constraint: NPLUS1 >= 1.

2: A(NPLUS1) -- DOUBLE PRECISION array Input
On entry: A(i) must be set to the value of the ith coefficient in the series, for i=1,2,...,n+1.

3: XCAP -- DOUBLE PRECISION Input

On entry: x, the argument at which the polynomial is to be evaluated. It should lie in the range -1 to +1, but a value just outside this range is permitted (see Section 6) to allow for possible rounding errors committed in the

transformation from x to x discussed in Section 3. Provided the recommended form of the transformation is used, a successful exit is thus assured whenever the value of x lies in the range x_{min} to x_{max}.

4: P -- DOUBLE PRECISION Output
On exit: the value of the polynomial.

5: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
ABS(XCAP) > 1.0 + 4(epsilon), where (epsilon) is the machine precision. In this case the value of P is set arbitrarily to zero.

IFAIL= 2
On entry NPLUS1 < 1.

```
          7. Accuracy

          The rounding errors committed are such that the computed value of
          the polynomial is exact for a slightly perturbed set of
          coefficients a +(delta)a . The ratio of the sum of the absolute
                        i        i
          values of the (delta)a  to the sum of the absolute values of the
                                i
          a  is less than a small multiple of (n+1) times machine
           i
          precision.

          8. Further Comments

          The time taken by the routine is approximately proportional to
          n+1.

          It is expected that a common use of E02AEF will be the evaluation
          of the polynomial approximations produced by E02ADF and E02AFF(*)

          9. Example

          Evaluate at 11 equally-spaced points in the interval -1<=x<=1 the
          polynomial of degree 4 with Chebyshev coefficients, 2.0, 0.5, 0.
          25, 0.125, 0.0625.

          The example program is written in a general form that will enable
          a polynomial of degree n in its Chebyshev-series form to be

          evaluated at m equally-spaced points in the interval -1<=x<=1.
          The program is self-starting in that any number of data sets can
          be supplied.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

                2                 (LWRK)

          3. Description

          This routine determines least-squares polynomial approximations
          of degrees up to k to the set of data points (x ,y ) with weights
                                                         r  r
          w , for r=1,2,...,m. The value of k, the maximum degree required,
           r
          is prescribed by the user. At each of the values XF , for r =
                                                             r
```

1,2,...,MF, of the independent variable x, the approximations and their derivatives up to order p_r are constrained to have one of the user-specified values YF_s, for s=1,2,...,n, where $n=MF+\sum_{r=1}^{MF} p_r$

The approximation of degree i has the property that, subject to the imposed contraints, it minimizes Σ_i, the sum of the squares of the weighted residuals ϵ_r for r=1,2,...,m where

$$\epsilon_r = w_r(y_r - f_i(x_r))$$

and $f_i(x_r)$ is the value of the polynomial approximation of degree i at the rth data point.

Each polynomial is represented in Chebyshev-series form with

normalised argument x. This argument lies in the range -1 to +1 and is related to the original variable x by the linear transformation

$$x= \frac{2x-(x_{max}+x_{min})}{(x_{max}-x_{min})}$$

where x_{min} and x_{max}, specified by the user, are respectively the lower and upper end-points of the interval of x over which the polynomials are to be defined.

The polynomial approximation of degree i can be written as

$$\frac{1}{2}a_{i,0}+a_{i,1}T_1(x)+...+a_{ij}T_j(x)+...+a_{ii}T_i(x)$$

where $T(x)$ is the Chebyshev polynomial of the first kind of

$_j$

degree j with argument x. For i=n,n+1,...,k, the routine produces the values of the coefficients a_{ij}, for j=0,1,...,i, together with the value of the root mean square residual, S_i, defined as

$$\sqrt{\frac{\sum_i}{(m'+n-i-1)}}$$, where m' is the number of data points with non-zero weight.

Values of the approximations may subsequently be computed using E02AEF or E02AKF.

First E02AGF determines a polynomial (mu)(x), of degree n-1, which satisfies the given constraints, and a polynomial (nu)(x), of degree n, which has value (or derivative) zero wherever a constrained value (or derivative) is specified. It then fits y_r -(mu)(x_r), for r=1,2,...,m with polynomials of the required

degree in x each with factor (nu)(x). Finally the coefficients of

(mu)(x) are added to the coefficients of these fits to give the coefficients of the constrained polynomial approximations to the data points (x_r,y_r), for r=1,2,...,m. The method employed is given in Hayes [3]: it is an extension of Forsythe's orthogonal polynomials method [2] as modified by Clenshaw [1].

5. Parameters

1: M -- INTEGER Input
On entry: the number m of data points to be fitted.
Constraint: M >= 1.

2: KPLUS1 -- INTEGER Input
On entry: k+1, where k is the maximum degree required.
Constraint: n+1<=KPLUS1<=m''+n, where n is the total number of constraints and m'' is the number of data points with non-zero weights and distinct abscissae which do not coincide with any of the XF(r).

3: NROWS -- INTEGER Input
On entry:
the first dimension of the array A as declared in the (sub)program from which E02AGF is called.
Constraint: NROWS >= KPLUS1.

4: XMIN -- DOUBLE PRECISION Input

5: XMAX -- DOUBLE PRECISION Input
On entry: the lower and upper end-points, respectively, of the interval $[x_{min},x_{max}]$. Unless there are specific reasons to the contrary, it is recommended that XMIN and XMAX be set respectively to the lowest and highest value among the x_r and XF(r). This avoids the danger of extrapolation provided there is a constraint point or data point with non-zero weight at each end-point. Constraint: XMAX > XMIN.

6: X(M) -- DOUBLE PRECISION array Input
On entry: the value x_r of the independent variable at the r th data point, for r=1,2,...,m. Constraint: the X(r) must be in non-decreasing order and satisfy XMIN <= X(r) <= XMAX.

7: Y(M) -- DOUBLE PRECISION array Input
On entry: Y(r) must contain y_r, the value of the dependent variable at the rth data point, for r=1,2,...,m.

8: W(M) -- DOUBLE PRECISION array Input
On entry: the weights w_r to be applied to the data points

x_r, for r=1,2...,m. For advice on the choice of weights see the Chapter Introduction. Negative weights are treated as positive. A zero weight causes the corresponding data point to be ignored. Zero weight should be given to any data point whose x and y values both coincide with those of a constraint (otherwise the denominators involved in the root-mean-square residuals s_i will be slightly in error).

9: MF -- INTEGER Input
On entry: the number of values of the independent variable at which a constraint is specified. Constraint: MF >= 1.

10: XF(MF) -- DOUBLE PRECISION array Input
On entry: the rth value of the independent variable at which a constraint is specified, for r = 1,2,...,MF. Constraint: these values need not be ordered but must be distinct and satisfy XMIN <= XF(r) <= XMAX.

11: YF(LYF) -- DOUBLE PRECISION array Input
On entry: the values which the approximating polynomials and their derivatives are required to take at the points specified in XF. For each value of XF(r), YF contains in successive elements the required value of the approximation, its first derivative, second derivative,..., p_r th derivative, for r = 1,2,...,MF. Thus the value which the kth derivative of each approximation (k=0 referring to the approximation itself) is required to take at the point XF(r) must be contained in YF(s), where

$$s=r+k+p_1+p_2+...+p_{r-1},$$

for k=0,1,...,p_r and r = 1,2,...,MF. The derivatives are with respect to the user's variable x.

12: LYF -- INTEGER Input
On entry:
the dimension of the array YF as declared in the (sub)program from which E02AGF is called.
Constraint: LYF>=n, where $n=MF+p_1+p_2+...+p_{MF}$.

13: IP(MF) -- INTEGER array Input
On entry: IP(r) must contain p_r, the order of the highest-order derivative specified at XF(r), for r = 1,2,...,MF. p_r=0 implies that the value of the approximation at XF(r) is

specified, but not that of any derivative. Constraint: IP(r) >= 0, for r=1,2,...,MF.

14: A(NROWS,KPLUS1) -- DOUBLE PRECISION array Output
On exit: A(i+1,j+1) contains the coefficient a_{ij} in the approximating polynomial of degree i, for i=n,n+1,...,k; j=0,1,...,i.

15: S(KPLUS1) -- DOUBLE PRECISION array Output
On exit: S(i+1) contains s_i, for i=n,n+1,...,k, the root-mean-square residual corresponding to the approximating polynomial of degree i. In the case where the number of data points with non-zero weight is equal to k+1-n, s_i is indeterminate: the routine sets it to zero. For the interpretation of the values of s_i and their use in selecting an appropriate degree, see Section 3.1 of the Chapter Introduction.

16: NP1 -- INTEGER Output
On exit: n+1, where n is the total number of constraint conditions imposed: $n=MF+p_1+p_2+...+p_{MF}$.

17: WRK(LWRK) -- DOUBLE PRECISION array Output
On exit: WRK contains weighted residuals of the highest degree of fit determined (k). The residual at x is in element 2(n+1)+3(m+k+1)+r, for r=1,2,...,m. The rest of the array is used as workspace.

18: LWRK -- INTEGER Input
On entry:
the dimension of the array WRK as declared in the (sub)program from which E02AGF is called.
Constraint: LWRK>=max(4*M+3*KPLUS1, 8*n+5*IPMAX+MF+10)+2*n+2 , where IPMAX = max(IP(R)).

19: IWRK(LIWRK) -- INTEGER array Workspace

20: LIWRK -- INTEGER Input
On entry:
the dimension of the array IWRK as declared in the (sub)program from which E02AGF is called.
Constraint: LIWRK>=2*MF+2.

21: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not

```
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     On entry M < 1,

     or       KPLUS1 < n + 1,

     or       NROWS < KPLUS1,

     or       MF < 1,

     or       LYF < n,

     or       LWRK is too small (see Section 5),

     or       LIWRK<2*MF+2.
     (Here n is the total number of constraint conditions.)

IFAIL= 2
     IP(r) < 0 for some r = 1,2,...,MF.

IFAIL= 3
     XMIN >= XMAX, or XF(r) is not in the interval XMIN to XMAX
     for some r = 1,2,...,MF, or the XF(r) are not distinct.

IFAIL= 4
     X(r) is not in the interval XMIN to XMAX for some
     r=1,2,...,M.

IFAIL= 5
     X(r) < X(r-1) for some r=2,3,...,M.

IFAIL= 6
     KPLUS1>m''+n, where m'' is the number of data points with
     non-zero weight and distinct abscissae which do not coincide
     with any XF(r). Thus there is no unique solution.

IFAIL= 7
     The polynomials (mu)(x) and/or (nu)(x) cannot be determined.
     The problem supplied is too ill-conditioned. This may occur
     when the constraint points are very close together, or large
     in number, or when an attempt is made to constrain high-
```

order derivatives.

7. Accuracy

No complete error analysis exists for either the interpolating algorithm or the approximating algorithm. However, considerable experience with the approximating algorithm shows that it is generally extremely satisfactory. Also the moderate number of constraints, of low order, which are typical of data fitting applications, are unlikely to cause difficulty with the interpolating routine.

8. Further Comments

The time taken by the routine to form the interpolating polynomial is approximately proportional to n^3, and that to form the approximating polynomials is very approximately proportional to m(k+1)(k+1-n).

To carry out a least-squares polynomial fit without constraints, use E02ADF. To carry out polynomial interpolation only, use E01AEF(*).

9. Example

The example program reads data in the following order, using the notation of the parameter list above:

MF

IP(i), XF(i), Y-value and derivative values (if any) at XF(i), for i= 1,2,...,MF

M

X(i), Y(i), W(i), for i=1,2,...,M

k, XMIN, XMAX

The output is:

the root-mean-square residual for each degree from n to k;

the Chebyshev coefficients for the fit of degree k;

the data points, and the fitted values and residuals for the fit of degree k.

The program is written in a generalized form which will read any

```
          number of data sets.

          The data set supplied specifies 5 data points in the interval [0.
          0,4.0] with unit weights, to which are to be fitted polynomials,
          p, of degrees up to 4, subject to the 3 constraints:

               p(0.0)=1.0,  p'(0.0)=-2.0,  p(4.0)=9.0.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

          E02 -- Curve and Surface Fitting                           E02AHF
                  E02AHF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          E02AHF determines the coefficients in the Chebyshev-series
          representation of the derivative of a polynomial given in
          Chebyshev-series form.

          2. Specification
```

```
       SUBROUTINE E02AHF (NP1, XMIN, XMAX, A, IA1, LA, PATM1,
      1                   ADIF, IADIF1, LADIF, IFAIL)
       INTEGER          NP1, IA1, LA, IADIF1, LADIF, IFAIL
       DOUBLE PRECISION XMIN, XMAX, A(LA), PATM1, ADIF(LADIF)
```

3. Description

This routine forms the polynomial which is the derivative of a given polynomial. Both the original polynomial and its derivative are represented in Chebyshev-series form. Given the coefficients a_i, for i=0,1,...,n, of a polynomial p(x) of degree n, where

$$p(x)=\frac{1}{2}a_0+a_1T_1(x)+...+a_nT_n(x)$$

the routine returns the coefficients a_i, for i=0,1,...,n-1, of the polynomial q(x) of degree n-1, where

$$q(x)=\frac{dp(x)}{dx}=\frac{1}{2}a_0+a_1T_1(x)+...+a_{n-1}T_{n-1}(x).$$

Here $T_j(x)$ denotes the Chebyshev polynomial of the first kind of degree j with argument x. It is assumed that the normalised variable x in the interval [-1,+1] was obtained from the user's original variable x in the interval $[x_{min},x_{max}]$ by the linear transformation

$$x=\frac{2x-(x_{max}+x_{min})}{x_{max}-x_{min}}$$

and that the user requires the derivative to be with respect to the variable x. If the derivative with respect to x is required, set $x_{max}=1$ and $x_{min}=-1$.

Values of the derivative can subsequently be computed, from the coefficients obtained, by using E02AKF.

The method employed is that of [1] modified to obtain the

derivative with respect to x. Initially setting $a_{n+1}=a_n=0$, the routine forms successively

$$a_{i-1}=a_{i+1}+\frac{2}{x_{max}-x_{min}}2ia_i, \quad i=n,n-1,...,1.$$

4. References

[1] Unknown (1961) Chebyshev-series. Modern Computing Methods, Chapter 8. NPL Notes on Applied Science (2nd Edition). 16 HMSO.

5. Parameters

1: NP1 -- INTEGER Input
On entry: n+1, where n is the degree of the given polynomial p(x). Thus NP1 is the number of coefficients in this polynomial. Constraint: NP1 >= 1.

2: XMIN -- DOUBLE PRECISION Input

3: XMAX -- DOUBLE PRECISION Input
On entry: the lower and upper end-points respectively of the interval $[x_{min},x_{max}]$. The Chebyshev-series

representation is in terms of the normalised variable x, where

$$x=\frac{2x-(x_{max}+x_{min})}{x_{max}-x_{min}}.$$

Constraint: XMAX > XMIN.

4: A(LA) -- DOUBLE PRECISION array Input
On entry: the Chebyshev coefficients of the polynomial p(x). Specifically, element 1 + i*IA1 of A must contain the coefficient a_i, for i=0,1,...,n. Only these n+1 elements will be accessed.

Unchanged on exit, but see ADIF, below.

5: IA1 -- INTEGER Input
On entry: the index increment of A. Most frequently the Chebyshev coefficients are stored in adjacent elements of A, and IA1 must be set to 1. However, if, for example, they are stored in A(1),A(4),A(7),..., then the value of IA1 must be 3. See also Section 8. Constraint: IA1 >= 1.

6: LA -- INTEGER Input
On entry:
the dimension of the array A as declared in the (sub)program from which E02AHF is called.
Constraint: LA>=1+(NP1-1)*IA1.

7: PATM1 -- DOUBLE PRECISION Output
On exit: the value of $p(x_{min})$. If this value is passed to the integration routine E02AJF with the coefficients of q(x), then the original polynomial p(x) is recovered, including its constant coefficient.

8: ADIF(LADIF) -- DOUBLE PRECISION array Output
On exit: the Chebyshev coefficients of the derived polynomial q(x). (The differentiation is with respect to the variable x). Specifically, element 1+i*IADIF1 of ADIF

contains the coefficient a_i, i=0,1,...n-1. Additionally element 1+n*IADIF1 is set to zero. A call of the routine may have the array name ADIF the same as A, provided that note is taken of the order in which elements are overwritten, when choosing the starting elements and increments IA1 and IADIF1: i.e., the coefficients $a_0,a_1,...,a_{i-1}$ must be intact

after coefficient a_i is stored. In particular, it is possible to overwrite the a_i completely by having IA1 = IADIF1, and the actual arrays for A and ADIF identical.

```
 9:  IADIF1 -- INTEGER                                      Input
     On entry: the index increment of ADIF. Most frequently the
     Chebyshev coefficients are required in adjacent elements of
     ADIF, and IADIF1 must be set to 1. However, if, for example,
     they are to be stored in ADIF(1),ADIF(4),ADIF(7),..., then
     the value of IADIF1 must be 3. See Section 8. Constraint:
     IADIF1 >= 1.

10:  LADIF -- INTEGER                                       Input
     On entry:
     the dimension of the array ADIF as declared in the
     (sub)program from which E02AHF is called.
     Constraint: LADIF>=1+(NP1-1)*IADIF1.

11:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).
```

6. Error Indicators and Warnings

Errors detected by the routine:

```
IFAIL= 1
     On entry NP1 < 1,

     or       XMAX <= XMIN,

     or       IA1 < 1,

     or       LA<=(NP1-1)*IA1,

     or       IADIF1 < 1,

     or       LADIF<=(NP1-1)*IADIF1.
```

7. Accuracy

There is always a loss of precision in numerical differentiation, in this case associated with the multiplication by 2i in the formula quoted in Section 3.

8. Further Comments

The time taken by the routine is approximately proportional to n+1.

```
         The increments IA1, IADIF1 are included as parameters to give a
         degree of flexibility which, for example, allows a polynomial in
         two variables to be differentiated with respect to either
         variable without rearranging the coefficients.

         9. Example

         Suppose a polynomial has been computed in Chebyshev-series form
         to fit data over the interval [-0.5,2.5]. The example program
         evaluates the 1st and 2nd derivatives of this polynomial at 4
         equally spaced points over the interval. (For the purposes of
         this example, XMIN, XMAX and the Chebyshev coefficients are
         simply supplied in DATA statements. Normally a program would
         first read in or generate data and compute the fitted
         polynomial.)

         The example program is not reproduced here. The source code for
         all example programs is distributed with the NAG Foundation
         Library software and should be available on-line.

         E02 -- Curve and Surface Fitting                           E02AJF
                 E02AJF -- NAG Foundation Library Routine Document

         Note: Before using this routine, please read the Users' Note for
         your implementation to check implementation-dependent details.
         The symbol (*) after a NAG routine name denotes a routine that is
```

not included in the Foundation Library.

1. Purpose

E02AJF determines the coefficients in the Chebyshev-series representation of the indefinite integral of a polynomial given in Chebyshev-series form.

2. Specification

```
       SUBROUTINE E02AJF (NP1, XMIN, XMAX, A, IA1, LA, QATM1,
      1                   AINT, IAINT1, LAINT, IFAIL)
       INTEGER          NP1, IA1, LA, IAINT1, LAINT, IFAIL
       DOUBLE PRECISION XMIN, XMAX, A(LA), QATM1, AINT(LAINT)
```

3. Description

This routine forms the polynomial which is the indefinite integral of a given polynomial. Both the original polynomial and its integral are represented in Chebyshev-series form. If supplied with the coefficients a_i, for i=0,1,...,n, of a polynomial p(x) of degree n, where

$$p(x)=\frac{1}{2}a_0+a_1T_1(x)+...+a_nT_n(x),$$

the routine returns the coefficients a'_i, for i=0,1,...,n+1, of the polynomial q(x) of degree n+1, where

$$q(x)=\frac{1}{2}a'_0+a'_1T_1(x)+...+a'_{n+1}T_{n+1}(x),$$

and

$$q(x)=\int p(x)dx.$$

Here $T_j(x)$ denotes the Chebyshev polynomial of the first kind of degree j with argument x. It is assumed that the normalised

variable x in the interval [-1,+1] was obtained from the user's original variable x in the interval $[x_{min}, x_{max}]$ by the linear transformation

$$\bar{x}=\frac{2x-(x_{max}+x_{min})}{x_{max}-x_{min}}$$

and that the user requires the integral to be with respect to the variable x. If the integral with respect to $\bar{x}$ is required, set $x_{max}=1$ and $x_{min}=-1$.

Values of the integral can subsequently be computed, from the coefficients obtained, by using E02AKF.

The method employed is that of Chebyshev-series [1] modified for integrating with respect to x. Initially taking $a_{n+1}=a_{n+2}=0$, the routine forms successively

$$a'_i = \frac{a_{i-1}-a_{i+1}}{2i} * \frac{x_{max}-x_{min}}{2}, \quad i=n+1,n,...,1.$$

The constant coefficient a'_0 is chosen so that q(x) is equal to a specified value, QATM1, at the lower end-point of the interval on which it is defined, i.e., $\bar{x}=-1$, which corresponds to $x=x_{min}$.

4. References

[1] Unknown (1961) Chebyshev-series. Modern Computing Methods, Chapter 8. NPL Notes on Applied Science (2nd Edition). 16 HMSO.

5. Parameters

1: NP1 -- INTEGER Input
On entry: n+1, where n is the degree of the given polynomial p(x). Thus NP1 is the number of coefficients in this polynomial. Constraint: NP1 >= 1.

2: XMIN -- DOUBLE PRECISION Input

3: XMAX -- DOUBLE PRECISION Input
On entry: the lower and upper end-points respectively of the interval $[x_{min},x_{max}]$. The Chebyshev-series

representation is in terms of the normalised variable x, where

$$x=\frac{2x-(x_{max}+x_{min})}{x_{max}-x_{min}}.$$

Constraint: XMAX > XMIN.

4: A(LA) -- DOUBLE PRECISION array Input
On entry: the Chebyshev coefficients of the polynomial p(x). Specifically, element 1+i*IA1 of A must contain the coefficient a_i, for i=0,1,...,n. Only these n+1 elements will be accessed.

Unchanged on exit, but see AINT, below.

5: IA1 -- INTEGER Input
On entry: the index increment of A. Most frequently the Chebyshev coefficients are stored in adjacent elements of A, and IA1 must be set to 1. However, if for example, they are stored in A(1),A(4),A(7),..., then the value of IA1 must be 3. See also Section 8. Constraint: IA1 >= 1.

6: LA -- INTEGER Input
On entry:
the dimension of the array A as declared in the (sub)program from which E02AJF is called.
Constraint: LA>=1+(NP1-1)*IA1.

7: QATM1 -- DOUBLE PRECISION Input
On entry: the value that the integrated polynomial is required to have at the lower end-point of its interval of

definition, i.e., at x=-1 which corresponds to $x=x_{min}$. Thus, QATM1 is a constant of integration and will normally be set to zero by the user.

```
 8:  AINT(LAINT) -- DOUBLE PRECISION array                 Output
     On exit: the Chebyshev coefficients of the integral q(x).
     (The integration is with respect to the variable x, and the
     constant coefficient is chosen so that q(x   ) equals QATM1)
                                                min
     Specifically, element 1+i*IAINT1 of AINT contains the
     coefficient a' , for i=0,1,...,n+1. A call of the routine
                   i
     may have the array name AINT the same as A, provided that
     note is taken of the order in which elements are overwritten
     when choosing starting elements and increments IA1 and
     IAINT1: i.e., the coefficients, a ,a ,...,a    must be
                                      0  1      i-2
     intact after coefficient a'  is stored. In particular it is
                                i
     possible to overwrite the a  entirely by having IA1 =
                                i
     IAINT1, and the actual array for A and AINT identical.

 9:  IAINT1 -- INTEGER                                      Input
     On entry: the index increment of AINT. Most frequently the
     Chebyshev coefficients are required in adjacent elements of
     AINT, and IAINT1 must be set to 1. However, if, for example,
     they are to be stored in AINT(1),AINT(4),AINT(7),..., then
     the value of IAINT1 must be 3. See also Section 8.
     Constraint: IAINT1 >= 1.

10:  LAINT -- INTEGER                                       Input
     On entry:
     the dimension of the array AINT as declared in the
     (sub)program from which E02AJF is called.
     Constraint: LAINT>=1+NP1*IAINT1.

11:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     On entry NP1 < 1,

     or       XMAX <= XMIN,
               or       IA1 < 1,

               or       LA<=(NP1-1)*IA1,

               or       IAINT1 < 1,

               or       LAINT<=NP1*IAINT1.

          7. Accuracy

          In general there is a gain in precision in numerical integration,
          in this case associated with the division by 2i in the formula
          quoted in Section 3.

          8. Further Comments

          The time taken by the routine is approximately proportional to
          n+1.

          The increments IA1, IAINT1 are included as parameters to give a
          degree of flexibility which, for example, allows a polynomial in
          two variables to be integrated with respect to either variable
          without rearranging the coefficients.

          9. Example

          Suppose a polynomial has been computed in Chebyshev-series form
          to fit data over the interval [-0.5,2.5]. The example program
          evaluates the integral of the polynomial from 0.0 to 2.0. (For
          the purpose of this example, XMIN, XMAX and the Chebyshev
          coefficients are simply supplied in DATA statements. Normally a
          program would read in or generate data and compute the fitted
          polynomial).

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

     E02AKF(3NAG)      Foundation Library (12/10/92)      E02AKF(3NAG)

          E02 -- Curve and Surface Fitting                           E02AKF
                  E02AKF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          E02AKF evaluates a polynomial from its Chebyshev-series
          representation, allowing an arbitrary index increment for
          accessing the array of coefficients.

          2. Specification

                 SUBROUTINE E02AKF (NP1, XMIN, XMAX, A, IA1, LA, X, RESULT,
                1                   IFAIL)
                 INTEGER          NP1, IA1, LA, IFAIL
                 DOUBLE PRECISION XMIN, XMAX, A(LA), X, RESULT

          3. Description

          If supplied with the coefficients a , for i=0,1,...,n, of a
                                             i

          polynomial p(x) of degree n, where

                               1
                         p(x)= -a +a T (x)+...+a T (x),
                               2 0  1 1        n n

          this routine returns the value of p(x) at a user-specified value

          of the variable x. Here T (x) denotes the Chebyshev polynomial of
                                   j
```

the first kind of degree j with argument x. It is assumed that

the independent variable x in the interval [-1,+1] was obtained from the user's original variable x in the interval $[x_{min},x_{max}]$ by the linear transformation

$$x=\frac{2x-(x_{max}+x_{min})}{x_{max}-x_{min}}.$$

The coefficients a_i may be supplied in the array A, with any increment between the indices of array elements which contain successive coefficients. This enables the routine to be used in surface fitting and other applications, in which the array might have two or more dimensions.

The method employed is based upon the three-term recurrence relation due to Clenshaw [1], with modifications due to Reinsch and Gentleman (see [4]). For further details of the algorithm and its use see Cox [2] and Cox and Hayes [3].

5. Parameters

```
 1: NP1 -- INTEGER                                        Input
    On entry: n+1, where n is the degree of the given
```

polynomial p(x). Constraint: NP1 >= 1.

2: XMIN -- DOUBLE PRECISION Input

3: XMAX -- DOUBLE PRECISION Input
On entry: the lower and upper end-points respectively of the interval $[x_{min},x_{max}]$. The Chebyshev-series

representation is in terms of the normalised variable x, where

$$\bar{x}=\frac{2x-(x_{max}+x_{min})}{x_{max}-x_{min}}.$$

Constraint: XMIN < XMAX.

4: A(LA) -- DOUBLE PRECISION array Input
On entry: the Chebyshev coefficients of the polynomial p(x). Specifically, element 1+i*IA1 must contain the coefficient a_i, for i=0,1,...,n. Only these n+1 elements will be accessed.

5: IA1 -- INTEGER Input
On entry: the index increment of A. Most frequently, the Chebyshev coefficients are stored in adjacent elements of A, and IA1 must be set to 1. However, if, for example, they are stored in A(1),A(4),A(7),..., then the value of IA1 must be 3. Constraint: IA1 >= 1.

6: LA -- INTEGER Input
On entry:
the dimension of the array A as declared in the (sub)program from which E02AKF is called.
Constraint: LA>=(NP1-1)*IA1+1.

7: X -- DOUBLE PRECISION Input
On entry: the argument x at which the polynomial is to be evaluated. Constraint: XMIN <= X <= XMAX.

8: RESULT -- DOUBLE PRECISION Output

On exit: the value of the polynomial p(x).

9: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not

familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
On entry NP1 < 1,

or IA1 < 1,

or LA<=(NP1-1)*IA1,

or XMIN >= XMAX.

IFAIL= 2
X does not satisfy the restriction XMIN <= X <= XMAX.

7. Accuracy

The rounding errors are such that the computed value of the polynomial is exact for a slightly perturbed set of coefficients a_i+(delta)a_i. The ratio of the sum of the absolute values of the (delta)a_i to the sum of the absolute values of the a_i is less than a small multiple of (n+1)*machine precision.

8. Further Comments

The time taken by the routine is approximately proportional to n+1.

9. Example

Suppose a polynomial has been computed in Chebyshev-series form to fit data over the interval [-0.5,2.5]. The example program evaluates the polynomial at 4 equally spaced points over the interval. (For the purposes of this example, XMIN, XMAX and the Chebyshev coefficients are supplied in DATA statements. Normally a program would first read in or generate data and compute the fitted polynomial.)

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

16.4.19 Weighted least-squares aprrox to data points

— nage.ht —

```
\begin{page}{manpageXXe02baf}{NAG Documentation: e02baf}
\beginscroll
\begin{verbatim}

     E02BAF(3NAG)      Foundation Library (12/10/92)      E02BAF(3NAG)

          E02 -- Curve and Surface Fitting                           E02BAF
                  E02BAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          E02BAF computes a weighted least-squares approximation to an
          arbitrary set of data points by a cubic spline with knots
          prescribed by the user. Cubic spline interpolation can also be
          carried out.

          2. Specification

                 SUBROUTINE E02BAF (M, NCAP7, X, Y, W, LAMDA, WORK1, WORK2,
                1                   C, SS, IFAIL)
                 INTEGER          M, NCAP7, IFAIL
                 DOUBLE PRECISION X(M), Y(M), W(M), LAMDA(NCAP7), WORK1(M),
                1                 WORK2(4*NCAP7), C(NCAP7), SS

          3. Description

          This routine determines a least-squares cubic spline
```

approximation s(x) to the set of data points (x_r,y_r) with weights

w_r, for r=1,2,...,m. The value of NCAP7 = n+7, where n is the number of intervals of the spline (one greater than the number of interior knots), and the values of the knots (lambda)$_5$,(lambda)$_6$,...,(lambda)$_{n+3}$, interior to the data interval, are prescribed by the user.

s(x) has the property that it minimizes (theta), the sum of squares of the weighted residuals (epsilon)$_r$, for r=1,2,...,m, where

$$(\text{epsilon})_r = w_r (y_r - s(x_r)).$$

The routine produces this minimizing value of (theta) and the

coefficients $c_1,c_2,...,c_q$, where q=n+3, in the B-spline representation

$$s(x) = \sum_{i=1}^{q} c_i N_i(x).$$

Here $N_i(x)$ denotes the normalised B-spline of degree 3 defined upon the knots (lambda)$_i$,(lambda)$_{i+1}$,...,(lambda)$_{i+4}$.

In order to define the full set of B-splines required, eight additional knots (lambda)$_1$,(lambda)$_2$,(lambda)$_3$,(lambda)$_4$ and (lambda)$_{n+4}$,(lambda)-$_{n+5}$,(lambda)$_{n+6}$,(lambda)$_{n+7}$ are inserted automatically by the routine. The first four of these are set equal to the smallest x_r and the last four to the largest x_r.

The representation of s(x) in terms of B-splines is the most

compact form possible in that only n+3 coefficients, in addition to the n+7 knots, fully define s(x).

The method employed involves forming and then computing the least-squares solution of a set of m linear equations in the coefficients c_i (i=1,2,...,n+3). The equations are formed using a recurrence relation for B-splines that is unconditionally stable (Cox [1], de Boor [5]), even for multiple (coincident) knots. The least-squares solution is also obtained in a stable manner by using orthogonal transformations, viz. a variant of Givens rotations (Gentleman [6] and [7]). This requires only one equation to be stored at a time. Full advantage is taken of the structure of the equations, there being at most four non-zero values of $N_i(x)$ for any value of x and hence at most four coefficients in each equation.

For further details of the algorithm and its use see Cox [2], [3] and [4].

Subsequent evaluation of s(x) from its B-spline representation may be carried out using E02BBF. If derivatives of s(x) are also required, E02BCF may be used. E02BDF can be used to compute the definite integral of s(x).

5. Parameters

1: M -- INTEGER Input
On entry: the number m of data points. Constraint: M >= MDIST >= 4, where MDIST is the number of distinct x values in the data.

2: NCAP7 -- INTEGER Input

On entry: n+7, where n is the number of intervals of the spline (which is one greater than the number of interior knots, i.e., the knots strictly within the range x_1 to x_m) over which the spline is defined. Constraint: 8 <= NCAP7 <= MDIST + 4, where MDIST is the number of distinct x values in the data.

3: X(M) -- DOUBLE PRECISION array Input
On entry: the values x_r of the independent variable (abscissa), for r=1,2,...,m. Constraint: $x_1 <= x_2 <= ... <= x_m$.

4: Y(M) -- DOUBLE PRECISION array Input
On entry: the values y_r of the dependent variable (ordinate), for r=1,2,...,m.

5: W(M) -- DOUBLE PRECISION array Input
On entry: the values w_r of the weights, for r=1,2,...,m. For advice on the choice of weights, see the Chapter Introduction. Constraint: W(r) > 0, for r=1,2,...,m.

6: LAMDA(NCAP7) -- DOUBLE PRECISION array Input/Output
On entry: LAMDA(i) must be set to the (i-4)th (interior)

knot, $(lambda)_i$, for i=5,6,...,n+3. Constraint: X(1) < LAMDA

```
     (5) <= LAMDA(6) <=... <= LAMDA(NCAP7-4) < X(M). On exit: the
     input values are unchanged, and LAMDA(i), for i = 1, 2, 3,
     4, NCAP7-3, NCAP7-2, NCAP7-1, NCAP7 contains the additional
     (exterior) knots introduced by the routine. For advice on
     the choice of knots, see Section 3.3 of the Chapter
     Introduction.

 7:  WORK1(M) -- DOUBLE PRECISION array                Workspace

 8:  WORK2(4*NCAP7) -- DOUBLE PRECISION array          Workspace

 9:  C(NCAP7) -- DOUBLE PRECISION array                   Output
     On exit: the coefficient c  of the B-spline N (x), for
                               i                  i

     i=1,2,...,n+3. The remaining elements of the array are not
     used.

10:  SS -- DOUBLE PRECISION                               Output
     On exit: the residual sum of squares, (theta).

11:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     The knots fail to satisfy the condition

     X(1) < LAMDA(5) <= LAMDA(6) <=... <= LAMDA(NCAP7-4) < X(M).
     Thus the knots are not in correct order or are not interior
     to the data interval.

IFAIL= 2
     The weights are not all strictly positive.

IFAIL= 3
     The values of X(r), for r = 1,2,...,M are not in non-
     decreasing order.

IFAIL= 4
     NCAP7 < 8 (so the number of interior knots is negative) or
     NCAP7 > MDIST + 4, where MDIST is the number of distinct x
     values in the data (so there cannot be a unique solution).

IFAIL= 5
     The conditions specified by Schoenberg and Whitney [8] fail
     to hold for at least one subset of the distinct data
     abscissae. That is, there is no subset of NCAP7-4 strictly
     increasing values, X(R(1)),X(R(2)),...,X(R(NCAP7-4)), among
     the abscissae such that
          X(R(1)) < LAMDA(1) < X(R(5)),

          X(R(2)) < LAMDA(2) < X(R(6)),

          ...

          X(R(NCAP7-8)) < LAMDA(NCAP7-8) < X(R(NCAP7-4)).
     This means that there is no unique solution: there are
     regions containing too many knots compared with the number
     of data points.

7. Accuracy

The rounding errors committed are such that the computed
coefficients are exact for a slightly perturbed set of ordinates
y +(delta)y . The ratio of the root-mean-square value for the
 r         r
(delta)y  to the root-mean-square value of the y  can be expected
        r                                      r
to be less than a small multiple of (kappa)*m*machine precision,
where (kappa) is a condition number for the problem. Values of
(kappa) for 20-30 practical data sets all proved to lie between
4.5 and 7.8 (see Cox [3]). (Note that for these data sets,
replacing the coincident end knots at the end-points x  and x
                                                      1      m
used in the routine by various choices of non-coincident exterior
knots gave values of (kappa) between 16 and 180. Again see Cox
[3] for further details.) In general we would not expect (kappa)
to be large unless the choice of knots results in near-violation
of the Schoenberg-Whitney conditions.

A cubic spline which adequately fits the data and is free from
spurious oscillations is more likely to be obtained if the knots
are chosen to be grouped more closely in regions where the
function (underlying the data) or its derivatives change more
rapidly than elsewhere.

8. Further Comments
```

```
          The time taken by the routine is approximately C*(2m+n+7)
          seconds, where C is a machine-dependent constant.

          Multiple knots are permitted as long as their multiplicity does
          not exceed 4, i.e., the complete set of knots must satisfy

          (lambda) <(lambda)   , for i=1,2,...,n+3, (cf. Section 6). At a
                  i         i+4
          knot of multiplicity one (the usual case), s(x) and its first two
          derivatives are continuous. At a knot of multiplicity two, s(x)
          and its first derivative are continuous. At a knot of
          multiplicity three, s(x) is continuous, and at a knot of
          multiplicity four, s(x) is generally discontinous.

          The routine can be used efficiently for cubic spline

          interpolation, i.e.,if m=n+3. The abscissae must then of course
          satisfy x <x <...<x . Recommended values for the knots in this
                   1  2      m

          case are (lambda) =x   , for i=5,6,...,n+3.
                           i  i-2

          9. Example

          Determine a weighted least-squares cubic spline approximation
          with five intervals (four interior knots) to a set of 14 given
          data points. Tabulate the data and the corresponding values of
          the approximating spline, together with the residual errors, and
          also the values of the approximating spline at points half-way
          between each pair of adjacent data points.

          The example program is written in a general form that will enable

          a cubic spline approximation with n intervals (n-1 interior
          knots) to be obtained to m data points, with arbitrary positive
          weights, and the approximation to be tabulated. Note that E02BBF
          is used to evaluate the approximating spline. The program is
          self-starting in that any number of data sets can be supplied.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

                 SUBROUTINE E02BBF (NCAP7, LAMDA, C, X, S, IFAIL)
                 INTEGER          NCAP7, IFAIL
                 DOUBLE PRECISION LAMDA(NCAP7), C(NCAP7), X, S

          3. Description

          This routine evaluates the cubic spline s(x) at a prescribed
          argument x from its augmented knot set (lambda) , for
                                                         i

          i=1,2,...,n+7, (see E02BAF) and from the coefficients c , for
                                                                 i
          i=1,2,...,q in its B-spline representation
```

$$s(x)=\sum_{i=1}^{q} c_i N_i(x)$$

Here $q=n+3$, where n is the number of intervals of the spline, and $N_i(x)$ denotes the normalised B-spline of degree 3 defined upon the knots $(\lambda)_i,(\lambda)_{i+1},...,(\lambda)_{i+4}$. The prescribed argument x must satisfy $(\lambda)_4<=x<=(\lambda)_{n+4}$.

It is assumed that $(\lambda)_j>=(\lambda)_{j-1}$, for $j=2,3,...,n+7$, and $(\lambda)_{n+4}>(\lambda)_4$.

The method employed is that of evaluation by taking convex combinations due to de Boor [4]. For further details of the algorithm and its use see Cox [1] and [3].

It is expected that a common use of E02BBF will be the evaluation of the cubic spline approximations produced by E02BAF. A generalization of E02BBF which also forms the derivative of s(x) is E02BCF. E02BCF takes about 50% longer than E02BBF.

[4] De Boor C (1972) On Calculating with B-splines. J. Approx. Theory. 6 50--62.

5. Parameters

1: NCAP7 -- INTEGER Input

On entry: n+7, where n is the number of intervals (one greater than the number of interior knots, i.e., the knots strictly within the range $(lambda)_4$ to $(lambda)_{n+4}$) over which the spline is defined. Constraint: NCAP7 >= 8.

2: LAMDA(NCAP7) -- DOUBLE PRECISION array Input
On entry: LAMDA(j) must be set to the value of the jth member of the complete set of knots, $(lambda)_j$ for j=1,2,...,n+7. Constraint: the LAMDA(j) must be in non-decreasing order with LAMDA(NCAP7-3) > LAMDA(4).

3: C(NCAP7) -- DOUBLE PRECISION array Input
On entry: the coefficient c_i of the B-spline $N_i(x)$, for i=1,2,...,n+3. The remaining elements of the array are not used.

4: X -- DOUBLE PRECISION Input
On entry: the argument x at which the cubic spline is to be evaluated. Constraint: LAMDA(4) <= X <= LAMDA(NCAP7-3).

5: S -- DOUBLE PRECISION Output
On exit: the value of the spline, s(x).

6: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
The argument X does not satisfy LAMDA(4) <= X <= LAMDA(NCAP7-3).

In this case the value of S is set arbitrarily to zero.

IFAIL= 2
NCAP7 < 8, i.e., the number of interior knots is negative.

7. Accuracy

The computed value of s(x) has negligible error in most practical situations. Specifically, this value has an absolute error bounded in modulus by $18*c_{max}$ * machine precision, where c_{max} is the largest in modulus of c_j, c_{j+1}, c_{j+2} and c_{j+3}, and j is an integer such that $(lambda)_{j+3} <= x <= (lambda)_{j+4}$. If c_j, c_{j+1}, c_{j+2} and c_{j+3} are all of the same sign, then the computed value of s(x) has a relative error not exceeding 20*machine precision in modulus. For further details see Cox [2].

8. Further Comments

The time taken by the routine is approximately C*(1+0.1*log(n+7)) seconds, where C is a machine-dependent constant.

Note: the routine does not test all the conditions on the knots given in the description of LAMDA in Section 5, since to do this would result in a computation time approximately linear in n+7 instead of log(n+7). All the conditions are tested in E02BAF, however.

9. Example

Evaluate at 9 equally-spaced points in the interval 1.0<=x<=9.0 the cubic spline with (augmented) knots 1.0, 1.0, 1.0, 1.0, 3.0, 6.0, 8.0, 9.0, 9.0, 9.0, 9.0 and normalised cubic B-spline coefficients 1.0, 2.0, 4.0, 7.0, 6.0, 4.0, 3.0.

The example program is written in a general form that will enable

a cubic spline with n intervals, in its normalised cubic B-spline form, to be evaluated at m equally-spaced points in the interval

LAMDA(4) <= x <= LAMDA(n+4). The program is self-starting in that any number of data sets may be supplied.

```
          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

          E02 -- Curve and Surface Fitting                           E02BCF
                  E02BCF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          E02BCF evaluates a cubic spline and its first three derivatives
          from its B-spline representation.

          2. Specification

                 SUBROUTINE E02BCF (NCAP7, LAMDA, C, X, LEFT, S, IFAIL)
                 INTEGER          NCAP7, LEFT, IFAIL
                 DOUBLE PRECISION LAMDA(NCAP7), C(NCAP7), X, S(4)

          3. Description

          This routine evaluates the cubic spline s(x) and its first three
          derivatives at a prescribed argument x. It is assumed that s(x)
```

is represented in terms of its B-spline coefficients c_i, for $i=1,2,\ldots,n+3$ and (augmented) ordered knot set $(\lambda)_i$, for $i=1,2,\ldots,n+7$, (see E02BAF), i.e.,

$$s(x)=\sum_{i=1}^{q} c_i N_i(x)$$

Here $q=n+3$, n is the number of intervals of the spline and $N_i(x)$ denotes the normalised B-spline of degree 3 (order 4) defined upon the knots $(\lambda)_i,(\lambda)_{i+1},\ldots,(\lambda)_{i+4}$. The prescribed argument x must satisfy

$$(\lambda)_4 <= x <= (\lambda)_{n+4}$$

At a simple knot $(\lambda)_i$ (i.e., one satisfying $(\lambda)_{i-1} < (\lambda)_i < (\lambda)_{i+1}$), the third derivative of the spline is in general discontinuous. At a multiple knot (i.e., two or more knots with the same value), lower derivatives, and even the spline itself, may be discontinuous. Specifically, at a point x=u where (exactly) r knots coincide (such a point is termed a knot of multiplicity r), the values of the derivatives of order 4-j, for j=1,2,...,r, are in general discontinuous. (Here 1<=r<=4;r>4 is not meaningful.) The user must specify whether the value at such a point is required to be the left- or right-hand derivative.

The method employed is based upon:

(i) carrying out a binary search for the knot interval containing the argument x (see Cox [3]),

(ii) evaluating the non-zero B-splines of orders 1,2,3 and 4 by recurrence (see Cox [2] and [3]),

(iii) computing all derivatives of the B-splines of order 4 by applying a second recurrence to these computed B-spline values (see de Boor [1]),

(iv) multiplying the 4th-order B-spline values and their derivative by the appropriate B-spline coefficients, and summing, to yield the values of s(x) and its derivatives.

E02BCF can be used to compute the values and derivatives of cubic spline fits and interpolants produced by E02BAF.

If only values and not derivatives are required, E02BBF may be used instead of E02BCF, which takes about 50% longer than E02BBF.

[3] Cox M G (1978) The Numerical Evaluation of a Spline from its B-spline Representation. J. Inst. Math. Appl. 21 135--143.

5. Parameters

1: NCAP7 -- INTEGER Input

On entry: n+7, where n is the number of intervals of the spline (which is one greater than the number of interior knots, i.e., the knots strictly within the range $(lambda)_4$ to $(lambda)_{n+4}$ over which the spline is defined).
Constraint: NCAP7 >= 8.

2: LAMDA(NCAP7) -- DOUBLE PRECISION array Input
On entry: LAMDA(j) must be set to the value of the jth member of the complete set of knots, $(lambda)_j$, for

j=1,2,...,n+7. Constraint: the LAMDA(j) must be in non-decreasing order with

LAMDA(NCAP7-3) > LAMDA(4).

3: C(NCAP7) -- DOUBLE PRECISION array Input

On entry: the coefficient c_i of the B-spline $N_i(x)$, for

i=1,2,...,n+3. The remaining elements of the array are not used.

4: X -- DOUBLE PRECISION Input
On entry: the argument x at which the cubic spline and its derivatives are to be evaluated. Constraint: LAMDA(4) <= X <= LAMDA(NCAP7-3).

5: LEFT -- INTEGER Input
On entry: specifies whether left- or right-hand values of the spline and its derivatives are to be computed (see Section 3). Left- or right-hand values are formed according to whether LEFT is equal or not equal to 1. If x does not coincide with a knot, the value of LEFT is immaterial. If x = LAMDA(4), right-hand values are computed, and if x = LAMDA (NCAP7-3), left-hand values are formed, regardless of the value of LEFT.

6: S(4) -- DOUBLE PRECISION array Output
On exit: S(j) contains the value of the (j-1)th derivative of the spline at the argument x, for j = 1,2,3,4. Note that S(1) contains the value of the spline.

7: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
NCAP7 < 8, i.e., the number of intervals is not positive.

IFAIL= 2
Either LAMDA(4) >= LAMDA(NCAP7-3), i.e., the range over which s(x) is defined is null or negative in length, or X is an invalid argument, i.e., X < LAMDA(4) or X > LAMDA(NCAP7-3).

7. Accuracy

The computed value of s(x) has negligible error in most practical situations. Specifically, this value has an absolute error bounded in modulus by $18*c_{max}$ * machine precision, where c_{max} is the largest in modulus of c_j, c_{j+1}, c_{j+2} and c_{j+3}, and j is an integer such that $(lambda)_{j+3}$ <=x<=$(lambda)_{j+4}$. If c_j, c_{j+1}, c_{j+2} and c_{j+3} are all of the same sign, then the computed value of s(x) has relative error bounded by 18*machine precision. For full details see Cox [3].

No complete error analysis is available for the computation of the derivatives of s(x). However, for most practical purposes the absolute errors in the computed derivatives should be small.

8. Further Comments

The time taken by this routine is approximately linear in

log(n+7).

Note: the routine does not test all the conditions on the knots given in the description of LAMDA in Section 5, since to do this

would result in a computation time approximately linear in n+7

instead of log(n+7). All the conditions are tested in E02BAF, however.

9. Example

Compute, at the 7 arguments x = 0, 1, 2, 3, 4, 5, 6, the left- and right-hand values and first 3 derivatives of the cubic spline defined over the interval 0<=x<=6 having the 6 interior knots x = 1, 3, 3, 3, 4, 4, the 8 additional knots 0, 0, 0, 0, 6, 6, 6, 6, and the 10 B-spline coefficients 10, 12, 13, 15, 22, 26, 24, 18, 14, 12.

The input data items (using the notation of Section 5) comprise the following values in the order indicated:

```
    n           m

    LAMDA(j),   for j= 1,2,...,NCAP7
```

```
              C(j),       for j= 1,2,...,NCAP7-4

              x(i),       for i=1,2,...,m

          The example program is written in a general form that will enable
          the values and derivatives of a cubic spline having an arbitrary
          number of knots to be evaluated at a set of arbitrary points. Any
          number of data sets may be supplied. The only changes required to
          the program relate to the dimensions of the arrays LAMDA and C.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          E02BDF computes the definite integral of a cubic spline from its
          B-spline representation.
```

2. Specification

```
      SUBROUTINE E02BDF (NCAP7, LAMDA, C, DEFINT, IFAIL)
      INTEGER          NCAP7, IFAIL
      DOUBLE PRECISION LAMDA(NCAP7), C(NCAP7), DEFINT
```

3. Description

This routine computes the definite integral of the cubic spline s(x) between the limits x=a and x=b, where a and b are respectively the lower and upper limits of the range over which s(x) is defined. It is assumed that s(x) is represented in terms of its B-spline coefficients c_i, for i=1,2,...,n+3 and (augmented) ordered knot set $(\lambda)_i$, for i=1,2,...,n+7, with $(\lambda)_i=a$, for i = 1,2,3,4 and $(\lambda)_i=b$, for i=n+4,n+5,n+6,n+7, (see E02BAF), i.e.,

$$s(x)=\sum_{i=1}^{q} c_i N_i(x).$$

Here q=n+3, n is the number of intervals of the spline and $N_i(x)$ denotes the normalised B-spline of degree 3 (order 4) defined upon the knots $(\lambda)_i,(\lambda)_{i+1},...,(\lambda)_{i+4}$.

The method employed uses the formula given in Section 3 of Cox [1].

E02BDF can be used to determine the definite integrals of cubic spline fits and interpolants produced by E02BAF.

4. References

[1] Cox M G (1975) An Algorithm for Spline Interpolation. J.

Inst. Math. Appl. 15 95--108.

5. Parameters

1: NCAP7 -- INTEGER Input

On entry: n+7, where n is the number of intervals of the spline (which is one greater than the number of interior knots, i.e., the knots strictly within the range a to b) over which the spline is defined. Constraint: NCAP7 >= 8.

2: LAMDA(NCAP7) -- DOUBLE PRECISION array Input

On entry: LAMDA(j) must be set to the value of the jth member of the complete set of knots, $(lambda)_j$ for j=1,2,...,n+7. Constraint: the LAMDA(j) must be in non-decreasing order with LAMDA(NCAP7-3) > LAMDA(4) and satisfy

LAMDA(1)=LAMDA(2)=LAMDA(3)=LAMDA(4)

and

LAMDA(NCAP7-3)=LAMDA(NCAP7-2)=LAMDA(NCAP7-1)=LAMDA(NCAP7).

3: C(NCAP7) -- DOUBLE PRECISION array Input

On entry: the coefficient c_i of the B-spline $N_i(x)$, for i=1,2,...,n+3. The remaining elements of the array are not used.

4: DEFINT -- DOUBLE PRECISION Output

On exit: the value of the definite integral of s(x) between the limits x=a and x=b, where $a=(lambda)_4$ and $b=(lambda)_{n+4}$.

5: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     NCAP7 < 8, i.e., the number of intervals is not positive.

IFAIL= 2
     At least one of the following restrictions on the knots is violated:

          LAMDA(NCAP7-3) > LAMDA(4),

          LAMDA(j) >= LAMDA(j-1),

     for j = 2,3,...,NCAP7, with equality in the cases j=2,3,4,NCAP7-2,NCAP7-1, and NCAP7.

7. Accuracy

The rounding errors are such that the computed value of the integral is exact for a slightly perturbed set of B-spline coefficients c_i differing in a relative sense from those supplied by no more than 2.2*(n+3)*machine precision.

8. Further Comments

The time taken by the routine is approximately proportional to

n+7.

9. Example

Determine the definite integral over the interval 0<=x<=6 of a cubic spline having 6 interior knots at the positions (lambda)=1, 3, 3, 3, 4, 4, the 8 additional knots 0, 0, 0, 0, 6, 6, 6, 6, and the 10 B-spline coefficients 10, 12, 13, 15, 22, 26, 24, 18, 14, 12.

The input data items (using the notation of Section 5) comprise the following values in the order indicated:

```
n

LAMDA(j) for j = 1,2,...,NCAP7
,

C(j),    for j = 1,2,...,NCAP7-3
```

```
          The example program is written in a general form that will enable
          the definite integral of a cubic spline having an arbitrary
          number of knots to be computed. Any number of data sets may be
          supplied. The only changes required to the program relate to the
          dimensions of the arrays LAMDA and C.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation

      1                 FP, WRK(LWRK)
       CHARACTER*1      START
```

3. Description

This routine determines a smooth cubic spline approximation s(x) to the set of data points (x_r,y_r), with weights w_r, for r=1,2,...,m.

The spline is given in the B-spline representation

$$s(x)=\sum_{i=1}^{n-4} c_i N_i(x) \qquad (1)$$

where $N_i(x)$ denotes the normalised cubic B-spline defined upon the knots $\lambda_i,\lambda_{i+1},...,\lambda_{i+4}$.

The total number n of these knots and their values $\lambda_1,...,\lambda_n$ are chosen automatically by the routine. The knots $\lambda_5,...,\lambda_{n-4}$ are the interior knots; they divide the approximation interval $[x_1,x_m]$ into n-7 sub-intervals. The coefficients $c_1,c_2,...,c_{n-4}$ are then determined as the solution of the following constrained minimization problem:

minimize

$$\eta=\sum_{i=5}^{n-4} \delta_i^2 \qquad (2)$$

subject to the constraint

m

```
                         --          2
               (theta)= >  (epsilon) <=S                 (3)
                         --          r
                         r=1

where: (delta)    stands for the discontinuity jump in the third
             i   order derivative of s(x) at the interior knot
           (lambda) ,
                         i

       (epsilon)  denotes the weighted residual w (y -s(x )),
                r                               r  r    r

and    S          is a non-negative number to be specified by
                  the user.
```

The quantity (eta) can be seen as a measure of the (lack of) smoothness of s(x), while closeness of fit is measured through (theta). By means of the parameter S, 'the smoothing factor', the user will then control the balance between these two (usually conflicting) properties. If S is too large, the spline will be too smooth and signal will be lost (underfit); if S is too small, the spline will pick up too much noise (overfit). In the extreme cases the routine will return an interpolating spline ((theta)=0) if S is set to zero, and the weighted least-squares cubic polynomial ((eta)=0) if S is set very large. Experimenting with S values between these two extremes should result in a good compromise. (See Section 8.2 for advice on choice of S.)

The method employed is outlined in Section 8.3 and fully described in Dierckx [1], [2] and [3]. It involves an adaptive strategy for locating the knots of the cubic spline (depending on the function underlying the data and on the value of S), and an iterative method for solving the constrained minimization problem once the knots have been determined.

Values of the computed spline, or of its derivatives or definite integral, can subsequently be computed by calling E02BBF, E02BCF or E02BDF, as described in Section 8.4.

5. Parameters

1: START -- CHARACTER*1 Input
On entry: START must be set to 'C' or 'W'.

If START = 'C' (Cold start), the routine will build up the knot set starting with no interior knots. No values need be assigned to the parameters N, LAMDA, WRK or IWRK.

If START = 'W' (Warm start), the routine will restart the knot-placing strategy using the knots found in a previous call of the routine. In this case, the parameters N, LAMDA, WRK, and IWRK must be unchanged from that previous call. This warm start can save much time in searching for a satisfactory value of S. Constraint: START = 'C' or 'W'.

2: M -- INTEGER Input
On entry: m, the number of data points. Constraint: M >= 4.

3: X(M) -- DOUBLE PRECISION array Input
On entry: the values x_r of the independent variable (abscissa) x, for r=1,2,...,m. Constraint: $x_1<x_2<...<x_m$

4: Y(M) -- DOUBLE PRECISION array Input
On entry: the values y_r of the dependent variable (ordinate) y, for r=1,2,...,m.

5: W(M) -- DOUBLE PRECISION array Input
On entry: the values w_r of the weights, for r=1,2,...,m. For advice on the choice of weights, see the Chapter Introduction, Section 2.1.2. Constraint: W(r) > 0, for r=1,2,...,m.

6: S -- DOUBLE PRECISION Input
On entry: the smoothing factor, S.

If S=0.0, the routine returns an interpolating spline.

If S is smaller than machine precision, it is assumed equal

```
         to zero.

         For advice on the choice of S, see Section 3 and Section 8.2
         Constraint: S >= 0.0.

     7:  NEST -- INTEGER                                        Input
         On entry: an over-estimate for the number, n, of knots
         required. Constraint: NEST >= 8. In most practical
         situations, NEST = M/2 is sufficient. NEST never needs to be
         larger than M + 4, the number of knots needed for
         interpolation (S = 0.0).

     8:  N -- INTEGER                                    Input/Output
         On entry: if the warm start option is used, the value of N
         must be left unchanged from the previous call. On exit: the
         total number, n, of knots of the computed spline.

     9:  LAMDA(NEST) -- DOUBLE PRECISION array           Input/Output
         On entry: if the warm start option is used, the values
         LAMDA(1), LAMDA(2),...,LAMDA(N) must be left unchanged from
         the previous call. On exit: the knots of the spline i.e.,
         the positions of the interior knots LAMDA(5), LAMDA(6),...
         ,LAMDA(N-4) as well as the positions of the additional knots
         LAMDA(1) = LAMDA(2) = LAMDA(3) = LAMDA(4) = x  and
                                                      1

         LAMDA(N-3) = LAMDA(N-2) = LAMDA(N-1) = LAMDA(N) = x  needed
                                                            m
         for the B-spline representation.

    10:  C(NEST) -- DOUBLE PRECISION array                     Output
         On exit: the coefficient c  of the B-spline N (x) in the
                                   i                  i
         spline approximation s(x), for i=1,2,...,n-4.

    11:  FP -- DOUBLE PRECISION                                Output
         On exit: the sum of the squared weighted residuals, (theta),
         of the computed spline approximation. If FP = 0.0, this is
         an interpolating spline. FP should equal S within a relative
         tolerance of 0.001 unless n=8 when the spline has no
         interior knots and so is simply a cubic polynomial. For
         knots to be inserted, S must be set to a value below the
         value of FP produced in this case.

    12:  WRK(LWRK) -- DOUBLE PRECISION array                Workspace
         On entry: if the warm start option is used, the values WRK
         (1),...,WRK(n) must be left unchanged from the previous
         call.

    13:  LWRK -- INTEGER                                        Input
```

```
     On entry:
     the dimension of the array WRK as declared in the
     (sub)program from which E02BEF is called.
     Constraint: LWRK>=4*M+16*NEST+41.

14:  IWRK(NEST) -- INTEGER array                        Workspace
     On entry: if the warm start option is used, the values IWRK
     (1), ..., IWRK(n) must be left unchanged from the previous
     call.

     This array is used as workspace.

15:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry START /= 'C' or 'W',

     or       M < 4,

     or       S < 0.0,

     or       S = 0.0 and NEST < M + 4,

     or       NEST < 8,

     or       LWRK<4*M+16*NEST+41.

IFAIL= 2
     The weights are not all strictly positive.

IFAIL= 3
     The values of X(r), for r=1,2,...,M, are not in strictly
     increasing order.

IFAIL= 4
     The number of knots required is greater than NEST. Try
     increasing NEST and, if necessary, supplying larger arrays
```

for the parameters LAMDA, C, WRK and IWRK. However, if NEST is already large, say NEST > M/2, then this error exit may indicate that S is too small.

IFAIL= 5
The iterative process used to compute the coefficients of the approximating spline has failed to converge. This error exit may occur if S has been set very small. If the error persists with increased S, consult NAG.

If IFAIL = 4 or 5, a spline approximation is returned, but it fails to satisfy the fitting criterion (see (2) and (3) in Section 3) - perhaps by only a small amount, however.

7. Accuracy

On successful exit, the approximation returned is such that its weighted sum of squared residuals FP is equal to the smoothing factor S, up to a specified relative tolerance of 0.001 - except that if n=8, FP may be significantly less than S: in this case the computed spline is simply a weighted least-squares polynomial approximation of degree 3, i.e., a spline with no interior knots.

8. Further Comments

8.1. Timing

The time taken for a call of E02BEF depends on the complexity of the shape of the data, the value of the smoothing factor S, and the number of data points. If E02BEF is to be called for different values of S, much time can be saved by setting START =

8.2. Choice of S

If the weights have been correctly chosen (see Section 2.1.2 of the Chapter Introduction), the standard deviation of $w_r y_r$ would be the same for all r, equal to (sigma), say. In this case, choosing the smoothing factor S in the range $(\sigma)^2(m\pm\sqrt{2m})$, as suggested by Reinsch [4], is likely to give a good start in the search for a satisfactory value. Otherwise, experimenting with different values of S will be required from the start, taking account of the remarks in Section 3.

In that case, in view of computation time and memory requirements, it is recommended to start with a very large value for S and so determine the least-squares cubic polynomial; the value returned for FP, call it FP_0, gives an upper bound for S.

Then progressively decrease the value of S to obtain closer fits - say by a factor of 10 in the beginning, i.e., $S=FP_0/10$, $S=FP_0/100$, and so on, and more carefully as the approximation shows more details.

The number of knots of the spline returned, and their location, generally depend on the value of S and on the behaviour of the function underlying the data. However, if E02BEF is called with START = 'W', the knots returned may also depend on the smoothing factors of the previous calls. Therefore if, after a number of trials with different values of S and START = 'W', a fit can finally be accepted as satisfactory, it may be worthwhile to call E02BEF once more with the selected value for S but now using START = 'C'. Often, E02BEF then returns an approximation with the same quality of fit but with fewer knots, which is therefore better if data reduction is also important.

8.3. Outline of Method Used

If S=0, the requisite number of knots is known in advance, i.e., n=m+4; the interior knots are located immediately as $(lambda)_i = x_{i-2}$, for i=5,6,...,n-4. The corresponding least-squares spline (see E02BAF) is then an interpolating spline and therefore a solution of the problem.

If S>0, a suitable knot set is built up in stages (starting with no interior knots in the case of a cold start but with the knot set found in a previous call if a warm start is chosen). At each stage, a spline is fitted to the data by least-squares (see E02BAF) and (theta), the weighted sum of squares of residuals, is computed. If (theta)>S, new knots are added to the knot set to reduce (theta) at the next stage. The new knots are located in intervals where the fit is particularly poor, their number depending on the value of S and on the progress made so far in reducing (theta). Sooner or later, we find that (theta)<=S and at that point the knot set is accepted. The routine then goes on to compute the (unique) spline which has this knot set and which satisfies the full fitting criterion specified by (2) and (3). The theoretical solution has (theta)=S. The routine computes the spline by an iterative scheme which is ended when (theta)=S within a relative tolerance of 0.001. The main part of each iteration consists of a linear least-squares computation of special form, done in a similarly stable and efficient manner as in E02BAF.

An exception occurs when the routine finds at the start that, even with no interior knots (n=8), the least-squares spline already has its weighted sum of squares of residuals <=S. In this case, since this spline (which is simply a cubic polynomial) also has an optimal value for the smoothness measure (eta), namely zero, it is returned at once as the (trivial) solution. It will usually mean that S has been chosen too large.

For further details of the algorithm and its use, see Dierckx [3]

8.4. Evaluation of Computed Spline

The value of the computed spline at a given value X may be obtained in the double precision variable S by the call:

```
       CALL E02BBF(N,LAMDA,C,X,S,IFAIL)
```

where N, LAMDA and C are the output parameters of E02BEF.

The values of the spline and its first three derivatives at a given value X may be obtained in the double precision array SDIF of dimension at least 4 by the call:

```
       CALL E02BCF(N,LAMDA,C,X,LEFT,SDIF,IFAIL)
```

where if LEFT = 1, left-hand derivatives are computed and if LEFT /= 1, right-hand derivatives are calculated. The value of LEFT is only relevant if X is an interior knot.

The value of the definite integral of the spline over the interval X(1) to X(M) can be obtained in the double precision variable SINT by the call:

```
       CALL E02BDF(N,LAMDA,C,SINT,IFAIL)
```

9. Example

This example program reads in a set of data values, followed by a set of values of S. For each value of S it calls E02BEF to compute a spline approximation, and prints the values of the knots and the B-spline coefficients c_i.

The program includes code to evaluate the computed splines, by calls to E02BBF, at the points x_r and at points mid-way between them. These values are not printed out, however; instead the results are illustrated by plots of the computed splines, together with the data points (indicated by *) and the positions of the knots (indicated by vertical lines): the effect of decreasing S can be clearly seen. (The plots were obtained by

```
          calling NAG Graphical Supplement routine J06FAF(*).)

                   Please see figures in printed Reference Manual

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

                  E02DAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          E02DAF forms a minimal, weighted least-squares bicubic spline
          surface fit with prescribed knots to a given set of data points.

          2. Specification

                 SUBROUTINE E02DAF (M, PX, PY, X, Y, F, W, LAMDA, MU,
                1                   POINT, NPOINT, DL, C, NC, WS, NWS, EPS,
                2                   SIGMA, RANK, IFAIL)
```

```
       INTEGER          M, PX, PY, POINT(NPOINT), NPOINT, NC, NWS,
      1                 RANK, IFAIL
       DOUBLE PRECISION X(M), Y(M), F(M), W(M), LAMDA(PX), MU(PY),
      1                 DL(NC), C(NC), WS(NWS), EPS, SIGMA
```

3. Description

This routine determines a bicubic spline fit s(x,y) to the set of data points (x_r,y_r,f_r) with weights w_r, for r=1,2,...,m. The two sets of internal knots of the spline, {(lambda)} and {(mu)}, associated with the variables x and y respectively, are prescribed by the user. These knots can be thought of as dividing the data region of the (x,y) plane into panels (see diagram in Section 5). A bicubic spline consists of a separate bicubic polynomial in each panel, the polynomials joining together with continuity up to the second derivative across the panel boundaries.

s(x,y) has the property that (Sigma), the sum of squares of its weighted residuals $(rho)_r$, for r=1,2,...,m, where

$$(rho)_r=w_r(s(x_r,y_r)-f_r), \qquad (1)$$

is as small as possible for a bicubic spline with the given knot sets. The routine produces this minimized value of (Sigma) and the coefficients c_{ij} in the B-spline representation of s(x,y) - see Section 8. E02DEF and E02DFF are available to compute values of the fitted spline from the coefficients c_{ij}.

The least-squares criterion is not always sufficient to determine the bicubic spline uniquely: there may be a whole family of splines which have the same minimum sum of squares. In these cases, the routine selects from this family the spline for which the sum of squares of the coefficients c_{ij} is smallest: in other words, the minimal least-squares solution. This choice, although arbitrary, reduces the risk of unwanted fluctuations in the spline fit. The method employed involves forming a system of m linear equations in the coefficients c_{ij} and then computing its least-squares solution, which will be the minimal least-squares solution when appropriate. The basis of the method is described in Hayes and Halliday [4]. The matrix of the equation is formed using a recurrence relation for B-splines which is numerically stable (see Cox [1] and de Boor [2] - the former contains the more elementary derivation but, unlike [2], does not cover the case of coincident knots). The least-squares solution is also obtained in a stable manner by using orthogonal transformations, viz. a variant of Givens rotation (see Gentleman [3]). This requires only one row of the matrix to be stored at a time. Advantage is taken of the stepped-band structure which the matrix possesses when the data points are suitably ordered, there being at most sixteen non-zero elements in any row because of the definition of B-splines. First the matrix is reduced to upper triangular form and then the diagonal elements of this triangle are examined in turn. When an element is encountered whose square, divided by the mean squared weight, is less than a threshold (epsilon), it is replaced by zero and the rest of the elements in its row are reduced to zero by rotations with the remaining rows. The rank of the system is taken to be the number of non-zero diagonal elements in the final triangle, and the non-zero rows of this triangle are used to compute the minimal least-squares solution. If all the diagonal elements are non-zero, the rank is equal to the number of coefficients c_{ij} and the solution obtained is the ordinary least-squares solution, which is unique in this case.

5. Parameters

```
 1:  M -- INTEGER                                          Input
     On entry: the number of data points, m. Constraint: M > 1.

 2:  PX -- INTEGER                                         Input

 3:  PY -- INTEGER                                         Input
     On entry: the total number of knots (lambda) and (mu)
     associated with the variables x and y, respectively.
     Constraint: PX >= 8 and PY >= 8.
```

(They are such that PX-8 and PY-8 are the corresponding numbers of interior knots.) The running time and storage required by the routine are both minimized if the axes are labelled so that PY is the smaller of PX and PY.

4: X(M) -- DOUBLE PRECISION array Input

5: Y(M) -- DOUBLE PRECISION array Input

6: F(M) -- DOUBLE PRECISION array Input
On entry: the co-ordinates of the data point (x_r,y_r,f_r), for r=1,2,...,m. The order of the data points is immaterial, but see the array POINT, below.

7: W(M) -- DOUBLE PRECISION array Input
On entry: the weight w_r of the rth data point. It is important to note the definition of weight implied by the equation (1) in Section 3, since it is also common usage to define weight as the square of this weight. In this routine, each w_r should be chosen inversely proportional to the (absolute) accuracy of the corresponding f_r, as expressed, for example, by the standard deviation or probable error of the f_r. When the f_r are all of the same accuracy, all the w_r may be set equal to 1.0.

8: LAMDA(PX) -- DOUBLE PRECISION array Input/Output
On entry: LAMDA(i+4) must contain the ith interior knot $(lambda)_{i+4}$ associated with the variable x, for i=1,2,...,PX-8. The knots must be in non-decreasing order and lie strictly within the range covered by the data values of x. A knot is a value of x at which the spline is allowed to be discontinuous in the third derivative with respect to x, though continuous up to the second derivative. This degree of continuity can be reduced, if the user requires, by the use of coincident knots, provided that no more than four knots are chosen to coincide at any point. Two, or three, coincident knots allow loss of continuity in, respectively, the second and first derivative with respect to x at the value of x at which they coincide. Four coincident knots split the spline surface into two independent parts. For choice of knots see Section 8. On exit: the interior knots LAMDA(5) to LAMDA(PX-4) are unchanged, and the segments LAMDA(1:4) and LAMDA(PX-3:PX)

```
     contain additional (exterior) knots introduced by the
     routine in order to define the full set of B-splines
     required. The four knots in the first segment are all set
     equal to the lowest data value of x and the other four
     additional knots are all set equal to the highest value:
     there is experimental evidence that coincident end-knots are
     best for numerical accuracy. The complete array must be left
     undisturbed if E02DEF or E02DFF is to be used subsequently.

 9:  MU(PY) -- DOUBLE PRECISION array                      Input
     On entry: MU(i+4) must contain the ith interior knot (mu)
                                                             i+4
     associated with the variable y, i=1,2,...,PY-8. The same
     remarks apply to MU as to LAMDA above, with Y replacing X,
     and y replacing x.

10:  POINT(NPOINT) -- INTEGER array                        Input
     On entry: indexing information usually provided by E02ZAF
     which enables the data points to be accessed in the order
     which produces the advantageous matrix structure mentioned
     in Section 3. This order is such that, if the (x,y) plane is
     thought of as being divided into rectangular panels by the
     two sets of knots, all data in a panel occur before data in
     succeeding panels, where the panels are numbered from bottom
     to top and then left to right with the usual arrangement of
     axes, as indicated in the diagram.

            Please see figure in printed Reference Manual

     A data point lying exactly on one or more panel sides is
     considered to be in the highest numbered panel adjacent to
     the point. E02ZAF should be called to obtain the array
     POINT, unless it is provided by other means.

11:  NPOINT -- INTEGER                                     Input
     On entry:
     the dimension of the array POINT as declared in the
     (sub)program from which E02DAF is called.
     Constraint: NPOINT >= M + (PX-7)*(PY-7).

12:  DL(NC) -- DOUBLE PRECISION array                     Output
     On exit: DL gives the squares of the diagonal elements of
     the reduced triangular matrix, divided by the mean squared
     weight. It includes those elements, less than (epsilon),
     which are treated as zero (see Section 3).

13:  C(NC) -- DOUBLE PRECISION array                      Output
     On exit: C gives the coefficients of the fit. C((PY-4)*(i-
     1)+j) is the coefficient c   of Section 3 and Section 8 for
                               ij
     i=1,2,...,PX-4 and j=1,2,...,PY-4. These coefficients are
     used by E02DEF or E02DFF to calculate values of the fitted
     function.

14:  NC -- INTEGER                                         Input
     On entry: the value (PX-4)*(PY-4).

15:  WS(NWS) -- DOUBLE PRECISION array                 Workspace

16:  NWS -- INTEGER                                        Input
     On entry:
     the dimension of the array WS as declared in the
     (sub)program from which E02DAF is called.
     Constraint: NWS>=(2*NC+1)*(3*PY-6)-2.

17:  EPS -- DOUBLE PRECISION                               Input
     On entry: a threshold (epsilon) for determining the
     effective rank of the system of linear equations. The rank
     is determined as the number of elements of the array DL (see
     below) which are non-zero. An element of DL is regarded as
     zero if it is less than (epsilon). Machine precision is a
     suitable value for (epsilon) in most practical applications
     which have only 2 or 3 decimals accurate in data. If some
     coefficients of the fit prove to be very large compared with
     the data ordinates, this suggests that (epsilon) should be
     increased so as to decrease the rank. The array DL will give
     a guide to appropriate values of (epsilon) to achieve this,
     as well as to the choice of (epsilon) in other cases where
     some experimentation may be needed to determine a value
     which leads to a satisfactory fit.

18:  SIGMA -- DOUBLE PRECISION                            Output
     On exit: (Sigma), the weighted sum of squares of residuals.
     This is not computed from the individual residuals but from
     the right-hand sides of the orthogonally-transformed linear
     equations. For further details see Hayes and Halliday [4]
     page 97. The two methods of computation are theoretically
     equivalent, but the results may differ because of rounding
     error.

19:  RANK -- INTEGER                                      Output
     On exit: the rank of the system as determined by the value
     of the threshold (epsilon). When RANK = NC, the least-
     squares solution is unique: in other cases the minimal
     least-squares solution is computed.

20:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.
```

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
At least one set of knots is not in non-decreasing order, or an interior knot is outside the range of the data values.

IFAIL= 2
More than four knots coincide at a single point, possibly because all data points have the same value of x (or y) or because an interior knot coincides with an extreme data value.

IFAIL= 3
Array POINT does not indicate the data points in panel order. Call E02ZAF to obtain a correct array.

IFAIL= 4
On entry M <= 1,

or PX < 8,

or PY < 8,

or NC /= (PX-4)*(PY-4),

or NWS is too small,

or NPOINT is too small.

IFAIL= 5
All the weights w_r are zero or rank determined as zero.

7. Accuracy

The computation of the B-splines and reduction of the observation matrix to triangular form are both numerically stable.

8. Further Comments

The time taken by this routine is approximately proportional to the number of data points, m, and to $(3*(PY-4)+4)^2$.

The B-spline representation of the bicubic spline is

$$s(x,y)=\sum_{ij} c_{ij} M_i(x)N_j(y)$$

summed over i=1,2,...,PX-4 and over j=1,2,...,PY-4. Here $M_i(x)$ and $N_j(y)$ denote normalised cubic B-splines,the former defined on the knots $(\lambda)_i,(\lambda)_{i+1},...,(\lambda)_{i+4}$ and the latter on the knots $(\mu)_j,(\mu)_{j+1},...,(\mu)_{j+4}$. For further details, see Hayes and Halliday [4] for bicubic splines and de Boor [2] for normalised B-splines.

The choice of the interior knots, which help to determine the spline's shape, must largely be a matter of trial and error. It is usually best to start with a small number of knots and, examining the fit at each stage, add a few knots at a time at places where the fit is particularly poor. In intervals of x or y where the surface represented by the data changes rapidly, in function value or derivatives, more knots will be needed than elsewhere. In some cases guidance can be obtained by analogy with the case of coincident knots: for example, just as three coincident knots can produce a discontinuity in slope, three close knots can produce rapid change in slope. Of course, such rapid changes in behaviour must be adequately represented by the data points, as indeed must the behaviour of the surface generally, if a satisfactory fit is to be achieved. When there is no rapid change in behaviour, equally-spaced knots will often suffice.

In all cases the fit should be examined graphically before it is accepted as satisfactory.

The fit obtained is not defined outside the rectangle

$$(\lambda)_4<=x<=(\lambda)_{PX-3} \quad , \quad (\mu)_4<=y<=(\mu)_{PY-3}$$

The reason for taking the extreme data values of x and y for these four knots is that, as is usual in data fitting, the fit cannot be expected to give satisfactory values outside the data region. If, nevertheless, the user requires values over a larger rectangle, this can be achieved by augmenting the data with two artificial data points (a,c,0) and (b,d,0) with zero weight, where a<=x<=b, c<=y<=d defines the enlarged rectangle. In the case when the data are adequate to make the least-squares solution unique (RANK = NC), this enlargement will not affect the fit over the original rectangle, except for possibly enlarged rounding errors, and will simply continue the bicubic polynomials in the panels bordering the rectangle out to the new boundaries: in other cases the fit will be affected. Even using the original rectangle there may be regions within it, particularly at its corners, which lie outside the data region and where, therefore, the fit will be unreliable. For example, if there is no data point in panel 1 of the diagram in Section 5, the least-squares criterion leaves the spline indeterminate in this panel: the minimal spline determined by the subroutine in this case passes through the value zero at the point ((lambda)$_4$,(mu)$_4$).

9. Example

This example program reads a value for (epsilon), and a set of data points, weights and knot positions. If there are more y knots than x knots, it interchanges the x and y axes. It calls E02ZAF to sort the data points into panel order, E02DAF to fit a bicubic spline to them, and E02DEF to evaluate the spline at the data points.

Finally it prints:

the weighted sum of squares of residuals computed from the linear equations;

the rank determined by E02DAF;

data points, fitted values and residuals in panel order;

the weighted sum of squares of the residuals;

the coefficients of the spline fit.

The program is written to handle any number of data sets.

Note: the data supplied in this example is not typical of a realistic problem: the number of data points would normally be much larger (in which case the array dimensions and the value of NWS in the program would have to be increased); and the value of (epsilon) would normally be much smaller on most machines (see Section 5; the relatively large value of 10^{-6} has been chosen in order to illustrate a minimal least-squares solution when RANK < NC; in this example NC = 24).

The example program is not reproduced here. The source code for

```
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

     E02DCF(3NAG)      Foundation Library (12/10/92)      E02DCF(3NAG)

          E02 -- Curve and Surface Fitting                           E02DCF
                  E02DCF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          E02DCF computes a bicubic spline approximation to a set of data
          values, given on a rectangular grid in the x-y plane. The knots
          of the spline are located automatically, but a single parameter
          must be specified to control the trade-off between closeness of
          fit and smoothness of fit.

          2. Specification

                 SUBROUTINE E02DCF (START, MX, X, MY, Y, F, S, NXEST,
                1                   NYEST, NX, LAMDA, NY, MU, C, FP, WRK,
                2                   LWRK, IWRK, LIWRK, IFAIL)
                 INTEGER          MX, MY, NXEST, NYEST, NX, NY, LWRK, IWRK
                1                 (LIWRK), LIWRK, IFAIL
                 DOUBLE PRECISION X(MX), Y(MY), F(MX*MY), S, LAMDA(NXEST),
     1                 MU(NYEST), C((NXEST-4)*(NYEST-4)), FP, WRK
     2                 (LWRK)
      CHARACTER*1      START
```

3. Description

This routine determines a smooth bicubic spline approximation $s(x,y)$ to the set of data points $(x_q,y_r,f_{q,r})$, for $q=1,2,...,m_x$ and $r=1,2,...,m_y$.

The spline is given in the B-spline representation

$$s(x,y)=\sum_{i=1}^{n_x-4}\sum_{j=1}^{n_y-4}c_{ij}M_i(x)N_j(y), \qquad (1)$$

where $M_i(x)$ and $N_j(y)$ denote normalised cubic B-splines, the former defined on the knots λ_i to λ_{i+4} and the latter on the knots μ_j to μ_{j+4}. For further details, see Hayes and Halliday [4] for bicubic splines and de Boor [1] for normalised B-splines.

The total numbers n_x and n_y of these knots and their values $\lambda_1,...,\lambda_{n_x}$ and $\mu_1,...,\mu_{n_y}$ are chosen automatically by the routine. The knots $\lambda_5,...,\lambda_{n_x-4}$ and $\mu_5,...,\mu_{n_y-4}$ are the interior knots; they divide the approximation domain $[x_1,x_{m_m}]*[y_1,y_{m_m}]$ into $(n_x-7)*(n_y-7)$ subpanels $[\lambda_i,\lambda_{i+1}]*[\mu_j,\mu_{j+1}]$, for $i=4,5,...,n_x-4$, $j=4,5,...,n_y-4$. Then, much as in the curve case (see E02BEF), the coefficients c_{ij} are determined as the solution of the following constrained minimization problem:

minimize

$$(\eta), \qquad (2)$$

subject to the constraint

$$(\theta)=\sum_{q=1}^{m_x}\sum_{r=1}^{m_y}(\epsilon)_{q,r}^2 <= S, \qquad (3)$$

where (eta) is a measure of the (lack of) smoothness of s(x,y). Its value depends on the discontinuity jumps in s(x,y) across the boundaries of the subpanels. It is zero only when there are no discontinuities and is positive otherwise, increasing with the size of the jumps (see Dierckx [2] for details).

$(\epsilon)_{q,r}$ denotes the residual $f_{q,r}-s(x_q,y_r)$,

and S is a non-negative number to be specified by the user.

By means of the parameter S, 'the smoothing factor', the user will then control the balance between smoothness and closeness of fit, as measured by the sum of squares of residuals in (3). If S is too large, the spline will be too smooth and signal will be lost (underfit); if S is too small, the spline will pick up too much noise (overfit). In the extreme cases the routine will return an interpolating spline ((theta)=0) if S is set to zero, and the least-squares bicubic polynomial ((eta)=0) if S is set very large. Experimenting with S-values between these two extremes should result in a good compromise. (See Section 8.3 for advice on choice of S.)

The method employed is outlined in Section 8.5 and fully described in Dierckx [2] and [3]. It involves an adaptive strategy for locating the knots of the bicubic spline (depending on the function underlying the data and on the value of S), and an iterative method for solving the constrained minimization problem once the knots have been determined.

Values of the computed spline can subsequently be computed by calling E02DEF or E02DFF as described in Section 8.6.

5. Parameters

1: START -- CHARACTER*1 Input
On entry: START must be set to 'C' or 'W'.

If START = 'C' (Cold start), the routine will build up the knot set starting with no interior knots. No values need be assigned to the parameters NX, NY, LAMDA, MU, WRK or IWRK.

If START = 'W' (Warm start), the routine will restart the knot-placing strategy using the knots found in a previous call of the routine. In this case, the parameters NX, NY, LAMDA, MU, WRK and IWRK must be unchanged from that previous call. This warm start can save much time in searching for a satisfactory value of S. Constraint: START = 'C' or 'W'.

2: MX -- INTEGER Input
On entry: m_x, the number of grid points along the x axis.
Constraint: MX >= 4.

3: X(MX) -- DOUBLE PRECISION array Input
On entry: X(q) must be set to x_q, the x co-ordinate of the qth grid point along the x axis, for $q=1,2,...,m_x$.
Constraint: $x_1<x_2<...<x_{m_x}$.

4: MY -- INTEGER Input
On entry: m_y, the number of grid points along the y axis.

y

Constraint: MY >= 4.

5: Y(MY) -- DOUBLE PRECISION array Input

On entry: Y(r) must be set to y_r, the y co-ordinate of the rth grid point along the y axis, for r=1,2,...,m_y.

Constraint: $y_1<y_2<...<y_{m_y}$.

6: F(MX*MY) -- DOUBLE PRECISION array Input

On entry: F(m_y*(q-1)+r) must contain the data value $f_{q,r}$, for q=1,2,...,m_x and r=1,2,...,m_y.

7: S -- DOUBLE PRECISION Input

On entry: the smoothing factor, S.

If S=0.0, the routine returns an interpolating spline.

If S is smaller than machine precision, it is assumed equal to zero.

For advice on the choice of S, see Section 3 and Section 8.3
Constraint: S >= 0.0.

8: NXEST -- INTEGER Input

9: NYEST -- INTEGER Input

On entry: an upper bound for the number of knots n_x and n_y required in the x- and y-directions respectively.

In most practical situations, NXEST =m_x/2 and NYEST m_y/2 is sufficient. NXEST and NYEST never need to be larger than m_x+4 and m_y+4 respectively, the numbers of knots needed for interpolation (S=0.0). See also Section 8.4. Constraint: NXEST >= 8 and NYEST >= 8.

10: NX -- INTEGER Input/Output

On entry: if the warm start option is used, the value of NX must be left unchanged from the previous call. On exit: the total number of knots, n_x, of the computed spline with respect to the x variable.

11: LAMDA(NXEST) -- DOUBLE PRECISION array Input/Output
On entry: if the warm start option is used, the values LAMDA(1), LAMDA(2),...,LAMDA(NX) must be left unchanged from the previous call. On exit: LAMDA contains the complete set of knots $(\text{lambda})_i$ associated with the x variable, i.e., the interior knots LAMDA(5), LAMDA(6), ..., LAMDA(NX-4) as well as the additional knots LAMDA(1) = LAMDA(2) = LAMDA(3) = LAMDA(4) = X(1) and LAMDA(NX-3) = LAMDA(NX-2) = LAMDA(NX-1) = LAMDA(NX) = X(MX) needed for the B-spline representation.

12: NY -- INTEGER Input/Output
On entry: if the warm start option is used, the value of NY must be left unchanged from the previous call. On exit: the total number of knots, n_y, of the computed spline with respect to the y variable.

13: MU(NYEST) -- DOUBLE PRECISION array Input/Output
On entry: if the warm start option is used, the values MU (1), MU(2),...,MU(NY) must be left unchanged from the previous call. On exit: MU contains the complete set of knots $(\text{mu})_i$ associated with the y variable, i.e., the interior knots MU(5), MU(6),...,MU(NY-4) as well as the additional knots MU(1) = MU(2) = MU(3) = MU(4) = Y(1) and MU (NY-3) = MU(NY-2) = MU(NY-1) = MU(NY) = Y(MY) needed for the B-spline representation.

14: C((NXEST-4)*(NYEST-4)) -- DOUBLE PRECISION array Output
On exit: the coefficients of the spline approximation. C($(n_y-4)*(i-1)+j$) is the coefficient c_{ij} defined in Section 3.

15: FP -- DOUBLE PRECISION Output
On exit: the sum of squared residuals, (theta), of the computed spline approximation. If FP = 0.0, this is an interpolating spline. FP should equal S within a relative tolerance of 0.001 unless NX = NY = 8, when the spline has no interior knots and so is simply a bicubic polynomial. For knots to be inserted, S must be set to a value below the value of FP produced in this case.

16: WRK(LWRK) -- DOUBLE PRECISION array Workspace
On entry: if the warm start option is used, the values WRK (1),...,WRK(4) must be left unchanged from the previous call.

This array is used as workspace.

```
17:  LWRK -- INTEGER                                          Input
     On entry:
     the dimension of the array WRK as declared in the
     (sub)program from which E02DCF is called.
     Constraint:
          LWRK>=4*(MX+MY)+11*(NXEST+NYEST)+NXEST*MY

                +max(MY,NXEST)+54.

18:  IWRK(LIWRK) -- INTEGER array                         Workspace
     On entry: if the warm start option is used, the values IWRK
     (1), ..., IWRK(3) must be left unchanged from the previous
     call.

     This array is used as workspace.

19:  LIWRK -- INTEGER                                         Input
     On entry:
     the dimension of the array IWRK as declared in the
     (sub)program from which E02DCF is called.
     Constraint: LIWRK >= 3 + MX + MY + NXEST + NYEST.

20:  IFAIL -- INTEGER                                  Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry START /= 'C' or 'W',

     or       MX < 4,

     or       MY < 4,

     or       S < 0.0,

     or       S = 0.0 and NXEST < MX + 4,

     or       S = 0.0 and NYEST < MY + 4,
     or      NXEST < 8,

     or      NYEST < 8,

     or      LWRK < 4*(MX+MY)+11*(NXEST+NYEST)+NXEST*MY+
                    +max(MY,NXEST)+54

     or      LIWRK < 3 + MX + MY + NXEST + NYEST.
```

IFAIL= 2
The values of X(q), for q = 1,2,...,MX, are not in strictly increasing order.

IFAIL= 3
The values of Y(r), for r = 1,2,...,MY, are not in strictly increasing order.

IFAIL= 4
The number of knots required is greater than allowed by NXEST and NYEST. Try increasing NXEST and/or NYEST and, if necessary, supplying larger arrays for the parameters LAMDA, MU, C, WRK and IWRK. However, if NXEST and NYEST are already large, say NXEST > MX/2 and NYEST > MY/2, then this error exit may indicate that S is too small.

IFAIL= 5
The iterative process used to compute the coefficients of the approximating spline has failed to converge. This error exit may occur if S has been set very small. If the error persists with increased S, consult NAG.

If IFAIL = 4 or 5, a spline approximation is returned, but it fails to satisfy the fitting criterion (see (2) and (3) in Section 3) -- perhaps by only a small amount, however.

7. Accuracy

On successful exit, the approximation returned is such that its sum of squared residuals FP is equal to the smoothing factor S, up to a specified relative tolerance of 0.001 - except that if $n_x=8$ and $n_y=8$, FP may be significantly less than S: in this case the computed spline is simply the least-squares bicubic polynomial approximation of degree 3, i.e., a spline with no interior knots.

8. Further Comments

8.1. Timing

The time taken for a call of E02DCF depends on the complexity of the shape of the data, the value of the smoothing factor S, and the number of data points. If E02DCF is to be called for different values of S, much time can be saved by setting START =

8.2. Weighting of Data Points

E02DCF does not allow individual weighting of the data values. If these were determined to widely differing accuracies, it may be better to use E02DDF. The computation time would be very much longer, however.

8.3. Choice of S

If the standard deviation of $f_{q,r}$ is the same for all q and r (the case for which this routine is designed - see Section 8.2.) and known to be equal, at least approximately, to (sigma), say, then following Reinsch [5] and choosing the smoothing factor S in the range $(sigma)^2$ (m+-\/2m), where $m=m_x m_y$, is likely to give a good start in the search for a satisfactory value. If the standard deviations vary, the sum of their squares over all the data points could be used. Otherwise experimenting with different values of S will be required from the start, taking account of the remarks in Section 3.

In that case, in view of computation time and memory requirements, it is recommended to start with a very large value for S and so determine the least-squares bicubic polynomial; the value returned for FP, call it FP_0, gives an upper bound for S. Then progressively decrease the value of S to obtain closer fits - say by a factor of 10 in the beginning, i.e., $S=FP_0/10$, $S=FP_0/100$, and so on, and more carefully as the approximation shows more details.

The number of knots of the spline returned, and their location, generally depend on the value of S and on the behaviour of the function underlying the data. However, if E02DCF is called with START = 'W', the knots returned may also depend on the smoothing factors of the previous calls. Therefore if, after a number of trials with different values of S and START = 'W', a fit can finally be accepted as satisfactory, it may be worthwhile to call E02DCF once more with the selected value for S but now using START = 'C'. Often, E02DCF then returns an approximation with the same quality of fit but with fewer knots, which is therefore better if data reduction is also important.

8.4. Choice of NXEST and NYEST

The number of knots may also depend on the upper bounds NXEST and NYEST. Indeed, if at a certain stage in E02DCF the number of knots in one direction (say n_x) has reached the value of its upper bound (NXEST), then from that moment on all subsequent knots are added in the other (y) direction. Therefore the user has the option of limiting the number of knots the routine locates in any direction. For example, by setting NXEST = 8 (the lowest allowable value for NXEST), the user can indicate that he wants an approximation which is a simple cubic polynomial in the variable x.

8.5. Outline of Method Used

If S=0, the requisite number of knots is known in advance, i.e., $n_x=m_x+4$ and $n_y=m_y+4$; the interior knots are located immediately as $(lambda)_i = x_{i-2}$ and $(mu)_j = y_{j-2}$, for $i=5,6,...,n_x-4$ and $j=5,6,...,n_y-4$. The corresponding least-squares spline is then an interpolating spline and therefore a solution of the problem.

If S>0, suitable knot sets are built up in stages (starting with no interior knots in the case of a cold start but with the knot set found in a previous call if a warm start is chosen). At each stage, a bicubic spline is fitted to the data by least-squares, and (theta), the sum of squares of residuals, is computed. If (theta)>S, new knots are added to one knot set or the other so as to reduce (theta) at the next stage. The new knots are located in intervals where the fit is particularly poor, their number depending on the value of S and on the progress made so far in reducing (theta). Sooner or later, we find that (theta)<=S and at that point the knot sets are accepted. The routine then goes on to compute the (unique) spline which has these knot sets and which satisfies the full fitting criterion specified by (2) and (3). The theoretical solution has (theta)=S. The routine computes the spline by an iterative scheme which is ended when (theta)=S within a relative tolerance of 0.001. The main part of each iteration consists of a linear least-squares computation of special form, done in a similarly stable and efficient manner as in E02BAF for least-squares curve fitting.

An exception occurs when the routine finds at the start that, even with no interior knots ($n_x=n_y=8$), the least-squares spline

```
                              x  y
already has its sum of residuals <=S. In this case, since this
spline (which is simply a bicubic polynomial) also has an optimal
value for the smoothness measure (eta), namely zero, it is
returned at once as the (trivial) solution. It will usually mean
that S has been chosen too large.
```

For further details of the algorithm and its use see Dierckx [2].

8.6. Evaluation of Computed Spline

The values of the computed spline at the points (TX(r),TY(r)), for r = 1,2,...,N, may be obtained in the double precision array FF, of length at least N, by the following code:

```
       IFAIL = 0
       CALL E02DEF(N,NX,NY,TX,TY,LAMDA,MU,C,FF,WRK,IWRK,IFAIL)
```

where NX, NY, LAMDA, MU and C are the output parameters of E02DCF , WRK is a double precision workspace array of length at least NY-4, and IWRK is an integer workspace array of length at least NY-4.

To evaluate the computed spline on a KX by KY rectangular grid of points in the x-y plane, which is defined by the x co-ordinates stored in TX(q), for q=1,2,...,KX, and the y co-ordinates stored in TY(r), for r=1,2,...,KY, returning the results in the double precision array FG which is of length at least KX*KY, the following call may be used:

```
      IFAIL = 0
      CALL E02DFF(KX,KY,NX,NY,TX,TY,LAMDA,MU,C,FG,WRK,LWRK,
     *            IWRK,LIWRK,IFAIL)
```

where NX, NY, LAMDA, MU and C are the output parameters of E02DCF , WRK is a double precision workspace array of length at least LWRK = min(NWRK1,NWRK2), NWRK1 = KX*4+NX, NWRK2 = KY*4+NY, and IWRK is an integer workspace array of length at least LIWRK = KY + NY - 4 if NWRK1 >= NWRK2, or KX + NX - 4 otherwise. The result of the spline evaluated at grid point (q,r) is returned in element (KY*(q-1)+r) of the array FG.

9. Example

```
This example program reads in values of MX, MY, x , for q = 1,2,.
                                                 q
            r
ordinates f    defined at the grid points (x ,y ). It then calls
           q,r                              q  r
E02DCF to compute a bicubic spline approximation for one
```

```
         specified value of S, and prints the values of the computed knots
         and B-spline coefficients. Finally it evaluates the spline at a
         small sample of points on a rectangular grid.

         The example program is not reproduced here. The source code for
         all example programs is distributed with the NAG Foundation
         Library software and should be available on-line.

         E02 -- Curve and Surface Fitting                           E02DDF
                 E02DDF -- NAG Foundation Library Routine Document

         Note: Before using this routine, please read the Users' Note for
         your implementation to check implementation-dependent details.
         The symbol (*) after a NAG routine name denotes a routine that is
         not included in the Foundation Library.

         1. Purpose

         E02DDF computes a bicubic spline approximation to a set of
         scattered data. The knots of the spline are located
         automatically, but a single parameter must be specified to
         control the trade-off between closeness of fit and smoothness of
         fit.

         2. Specification

                SUBROUTINE E02DDF (START, M, X, Y, F, W, S, NXEST, NYEST,
     1                   NX, LAMDA, NY, MU, C, FP, RANK, WRK,
     2                   LWRK, IWRK, LIWRK, IFAIL)
      INTEGER          M, NXEST, NYEST, NX, NY, RANK, LWRK, IWRK
     1                 (LIWRK), LIWRK, IFAIL
      DOUBLE PRECISION X(M), Y(M), F(M), W(M), S, LAMDA(NXEST),
     1                 MU(NYEST), C((NXEST-4)*(NYEST-4)), FP, WRK
     2                 (LWRK)
      CHARACTER*1      START
```

3. Description

This routine determines a smooth bicubic spline approximation $s(x,y)$ to the set of data points (x_r,y_r,f_r) with weights w_r, for $r=1,2,...,m$.

The approximation domain is considered to be the rectangle $[x_{min},x_{max}]*[y_{min},y_{max}]$, where x_{min} (y_{min}) and x_{max} (y_{max}) denote the lowest and highest data values of x (y).

The spline is given in the B-spline representation

$$s(x,y)=\sum_{i=1}^{n_x-4}\sum_{j=1}^{n_y-4} c_{ij} M_i(x)N_j(y), \qquad (1)$$

where $M_i(x)$ and $N_j(y)$ denote normalised cubic B-splines, the former defined on the knots $(\lambda)_i$ to $(\lambda)_{i+4}$ and the latter on the knots $(\mu)_j$ to $(\mu)_{j+4}$. For further details, see Hayes and Halliday [4] for bicubic splines and de Boor [1] for normalised B-splines.

The total numbers n_x and n_y of these knots and their values $(\lambda)_1,...,(\lambda)_{n_x}$ and $(\mu)_1,...,(\mu)_{n_y}$ are chosen automatically by the routine. The knots $(\lambda)_5,...,$ $(\lambda)_{n_x-4}$ and $(\mu)_5,...,(\mu)_{n_y-4}$ are the interior knots; they divide the approximation domain $[x_{min},x_{max}]*[y_{min},y_{max}]$ into (

$n_x-7)*(n_y-7)$ subpanels $[(\lambda)_i^{min},(\lambda)_{i+1}^{max}]*[(\mu)_j^{min},(\mu)_{j+1}^{max}]$, for $i=4,5,\ldots,n_x-4$; $j=4,5,\ldots,n_y-4$. Then, much as in the curve case (see E02BEF), the coefficients c_{ij} are determined as the solution of the following constrained minimization problem:

minimize

$$(\eta), \qquad (2)$$

subject to the constraint

$$(\theta)=\sum_{r=1}^{m}(\epsilon)_r^2\le S \qquad (3)$$

where: (η) is a measure of the (lack of) smoothness of s(x,y). Its value depends on the discontinuity jumps in s(x,y) across the boundaries of the subpanels. It is zero only when there are no discontinuities and is positive otherwise, increasing with the size of the jumps (see Dierckx [2] for details).

$(\epsilon)_r$ denotes the weighted residual $w_r(f_r-s(x_r,y_r))$,

and S is a non-negative number to be specified by the user.

By means of the parameter S, 'the smoothing factor', the user will then control the balance between smoothness and closeness of fit, as measured by the sum of squares of residuals in (3). If S is too large, the spline will be too smooth and signal will be lost (underfit); if S is too small, the spline will pick up too much noise (overfit). In the extreme cases the method would return an interpolating spline ($(\theta)=0$) if S were set to zero, and returns the least-squares bicubic polynomial ($(\eta)=0$) if S is set very large. Experimenting with S-values between these two extremes should result in a good compromise. (See Section 8.2 for advice on choice of S.) Note however, that this routine, unlike E02BEF and E02DCF, does not allow S to be set exactly to zero: to compute an interpolant to scattered data, E01SAF or E01SEF should be used.

The method employed is outlined in Section 8.5 and fully described in Dierckx [2] and [3]. It involves an adaptive strategy for locating the knots of the bicubic spline (depending on the function underlying the data and on the value of S), and an iterative method for solving the constrained minimization problem once the knots have been determined.

Values of the computed spline can subsequently be computed by calling E02DEF or E02DFF as described in Section 8.6.

5. Parameters

1: START -- CHARACTER*1 Input
On entry: START must be set to 'C' or 'W'.

If START = 'C' (Cold start), the routine will build up the knot set starting with no interior knots. No values need be assigned to the parameters NX, NY, LAMDA, MU or WRK.

If START = 'W' (Warm start), the routine will restart the knot-placing strategy using the knots found in a previous call of the routine. In this case, the parameters NX, NY, LAMDA, MU and WRK must be unchanged from that previous call. This warm start can save much time in searching for a satisfactory value of S. Constraint: START = 'C' or 'W'.

2: M -- INTEGER Input
On entry: m, the number of data points.

The number of data points with non-zero weight (see W below) must be at least 16.

3: X(M) -- DOUBLE PRECISION array Input

4: Y(M) -- DOUBLE PRECISION array Input

5: F(M) -- DOUBLE PRECISION array Input
On entry: X(r), Y(r), F(r) must be set to the co-ordinates of (x_r,y_r,f_r), the rth data point, for r=1,2,...,m. The order of the data points is immaterial.

6: W(M) -- DOUBLE PRECISION array Input
On entry: W(r) must be set to w_r, the rth value in the set of weights, for r=1,2,...,m. Zero weights are permitted and the corresponding points are ignored, except when determining x_{min}, x_{max}, y_{min} and y_{max} (see Section 8.4). For advice on the choice of weights, see Section 2.1.2 of the Chapter Introduction. Constraint: the number of data points with non-zero weight must be at least 16.

7: S -- DOUBLE PRECISION Input
On entry: the smoothing factor, S.

For advice on the choice of S, see Section 3 and Section 8.2 . Constraint: S > 0.0.

8: NXEST -- INTEGER Input

9: NYEST -- INTEGER Input
On entry: an upper bound for the number of knots n_x and n_y required in the x- and y-directions respectively.

In most practical situations, NXEST = NYEST = $4+\sqrt{m/2}$ is sufficient. See also Section 8.3. Constraint: NXEST >= 8 and NYEST >= 8.

10: NX -- INTEGER Input/Output
On entry: if the warm start option is used, the value of NX must be left unchanged from the previous call. On exit: the total number of knots, n_x, of the computed spline with respect to the x variable.

11: LAMDA(NXEST) -- DOUBLE PRECISION array Input/Output
On entry: if the warm start option is used, the values LAMDA

(1), LAMDA(2),...,LAMDA(NX) must be left unchanged from the previous call. On exit: LAMDA contains the complete set of knots $(lambda)_i$ associated with the x variable, i.e., the interior knots LAMDA(5), LAMDA(6),...,LAMDA(NX-4) as well as the additional knots LAMDA(1) = LAMDA(2) = LAMDA(3) = LAMDA (4) = x_{min} and LAMDA(NX-3) = LAMDA(NX-2) = LAMDA(NX-1) = LAMDA(NX) = x_{max} needed for the B-spline representation (where x_{min} and x_{max} are as described in Section 3).

12: NY -- INTEGER Input/Output
On entry: if the warm start option is used, the value of NY must be left unchanged from the previous call. On exit: the total number of knots, n_y, of the computed spline with respect to the y variable.

13: MU(NYEST) -- DOUBLE PRECISION array Input/Output
On entry: if the warm start option is used, the values MU(1) MU(2),...,MU(NY) must be left unchanged from the previous call. On exit: MU contains the complete set of knots $(mu)_i$ associated with the y variable, i.e., the interior knots MU (5), MU(6),...,MU(NY-4) as well as the additional knots MU (1) = MU(2) = MU(3) = MU(4) = y_{min} and MU(NY-3) = MU(NY-2) = MU(NY-1) = MU(NY) = y_{max} needed for the B-spline representation (where y_{min} and y_{max} are as described in Section 3).

14: C((NXEST-4)*(NYEST-4)) -- DOUBLE PRECISION array Output
On exit: the coefficients of the spline approximation. C($(n_y$ -4)*(i-1)+j) is the coefficient c_{ij} defined in Section 3.

15: FP -- DOUBLE PRECISION Output
On exit: the weighted sum of squared residuals, (theta), of the computed spline approximation. FP should equal S within a relative tolerance of 0.001 unless NX = NY = 8, when the spline has no interior knots and so is simply a bicubic polynomial. For knots to be inserted, S must be set to a value below the value of FP produced in this case.

16: RANK -- INTEGER Output
On exit: RANK gives the rank of the system of equations used

```
     to compute the final spline (as determined by a suitable
     machine-dependent threshold). When RANK = (NX-4)*(NY-4), the
     solution is unique; otherwise the system is rank-deficient
     and the minimum-norm solution is computed. The latter case
     may be caused by too small a value of S.

17:  WRK(LWRK) -- DOUBLE PRECISION array                Workspace
     On entry: if the warm start option is used, the value of WRK
     (1) must be left unchanged from the previous call.

     This array is used as workspace.

18:  LWRK -- INTEGER                                        Input
     On entry:
     the dimension of the array WRK as declared in the
     (sub)program from which E02DDF is called.
     Constraint: LWRK >= (7*u*v+25*w)*(w+1)+2*(u+v+4*M)+23*w+56,

     where

     u=NXEST-4, v=NYEST-4, and w=max(u,v).

     For some problems, the routine may need to compute the
     minimal least-squares solution of a rank-deficient system of
     linear equations (see Section 3). The amount of workspace
     required to solve such problems will be larger than
     specified by the value given above, which must be increased
     by an amount, LWRK2 say. An upper bound for LWRK2 is given
     by 4*u*v*w+2*u*v+4*w, where u, v and w are as above.
     However, if there are enough data points, scattered
     uniformly over the approximation domain, and if the
     smoothing factor S is not too small, there is a good chance
     that this extra workspace is not needed. A lot of memory
     might therefore be saved by assuming LWRK2 = 0.

19:  IWRK(LIWRK) -- INTEGER array                       Workspace

20:  LIWRK -- INTEGER                                       Input
     On entry:
     the dimension of the array IWRK as declared in the
     (sub)program from which E02DDF is called.
     Constraint: LIWRK>=M+2*(NXEST-7)*(NYEST-7).

21:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry START /= 'C' or 'W',

     or       the number of data points with non-zero weight <
              16,

     or       S <= 0.0,

     or       NXEST < 8,

     or       NYEST < 8,

     or       LWRK < (7*u*v+25*w)*(w+1)+2*(u+v+4*M)+23*w+56,
              where u = NXEST - 4, v = NYEST - 4 and w=max(u,v),

     or       LIWRK <M+2*(NXEST-7)*(NYEST-7).

IFAIL= 2
     On entry either all the X(r), for r = 1,2,...,M, are equal,
     or all the Y(r), for r = 1,2,...,M, are equal.

IFAIL= 3
     The number of knots required is greater than allowed by
     NXEST and NYEST. Try increasing NXEST and/or NYEST and, if
     necessary, supplying larger arrays for the parameters LAMDA,
     MU, C, WRK and IWRK. However, if NXEST and NYEST are already

     large, say NXEST, NYEST > 4 + \/M/2, then this error exit
     may indicate that S is too small.

IFAIL= 4
     No more knots can be added because the number of B-spline
     coefficients (NX-4)*(NY-4) already exceeds the number of
     data points M. This error exit may occur if either of S or M
     is too small.

IFAIL= 5
     No more knots can be added because the additional knot would
     (quasi) coincide with an old one. This error exit may occur
     if too large a weight has been given to an inaccurate data
```

point, or if S is too small.

IFAIL= 6
The iterative process used to compute the coefficients of the approximating spline has failed to converge. This error exit may occur if S has been set very small. If the error persists with increased S, consult NAG.

IFAIL= 7
LWRK is too small; the routine needs to compute the minimal least-squares solution of a rank-deficient system of linear equations, but there is not enough workspace. There is no approximation returned but, having saved the information contained in NX, LAMDA, NY, MU and WRK, and having adjusted the value of LWRK and the dimension of array WRK accordingly, the user can continue at the point the program was left by calling E02DDF with START = 'W'. Note that the requested value for LWRK is only large enough for the current phase of the algorithm. If the routine is restarted with LWRK set to the minimum value requested, a larger request may be made at a later stage of the computation. See Section 5 for the upper bound on LWRK. On soft failure, the minimum requested value for LWRK is returned in IWRK(1) and the safe value for LWRK is returned in IWRK(2).

If IFAIL = 3,4,5 or 6, a spline approximation is returned, but it fails to satisfy the fitting criterion (see (2) and (3) in Section 3 -- perhaps only by a small amount, however.

7. Accuracy

On successful exit, the approximation returned is such that its weighted sum of squared residuals FP is equal to the smoothing factor S, up to a specified relative tolerance of 0.001 - except that if $n_x=8$ and $n_y=8$, FP may be significantly less than S: in this case the computed spline is simply the least-squares bicubic polynomial approximation of degree 3, i.e., a spline with no interior knots.

8. Further Comments

8.1. Timing

The time taken for a call of E02DDF depends on the complexity of the shape of the data, the value of the smoothing factor S, and the number of data points. If E02DDF is to be called for different values of S, much time can be saved by setting START = It should be noted that choosing S very small considerably increases computation time.

8.2. Choice of S

If the weights have been correctly chosen (see Section 2.1.2 of the Chapter Introduction), the standard deviation of $w_r f_r$ would be the same for all r, equal to (sigma), say. In this case, choosing the smoothing factor S in the range $(sigma)^2 (m+-\/2m)$, as suggested by Reinsch [6], is likely to give a good start in the search for a satisfactory value. Otherwise, experimenting with different values of S will be required from the start.

In that case, in view of computation time and memory requirements, it is recommended to start with a very large value for S and so determine the least-squares bicubic polynomial; the value returned for FP, call it FP_0, gives an upper bound for S. Then progressively decrease the value of S to obtain closer fits - say by a factor of 10 in the beginning, i.e., $S=FP_0/10$, $S=FP_0/100$, and so on, and more carefully as the approximation shows more details.

To choose S very small is strongly discouraged. This considerably increases computation time and memory requirements. It may also cause rank-deficiency (as indicated by the parameter RANK) and endanger numerical stability.

The number of knots of the spline returned, and their location, generally depend on the value of S and on the behaviour of the function underlying the data. However, if E02DDF is called with START = 'W', the knots returned may also depend on the smoothing factors of the previous calls. Therefore if, after a number of trials with different values of S and START = 'W', a fit can finally be accepted as satisfactory, it may be worthwhile to call E02DDF once more with the selected value for S but now using START = 'C'. Often, E02DDF then returns an approximation with the same quality of fit but with fewer knots, which is therefore better if data reduction is also important.

8.3. Choice of NXEST and NYEST

The number of knots may also depend on the upper bounds NXEST and NYEST. Indeed, if at a certain stage in E02DDF the number of knots in one direction (say n_x) has reached the value of its upper bound (NXEST), then from that moment on all subsequent knots are added in the other (y) direction. This may indicate that the value of NXEST is too small. On the other hand, it gives the user the option of limiting the number of knots the routine locates in any direction. For example, by setting NXEST = 8 (the lowest allowable value for NXEST), the user can indicate that he wants an approximation which is a simple cubic polynomial in the variable x.

8.4. Restriction of the approximation domain

The fit obtained is not defined outside the rectangle $[(lambda)_4,(lambda)_{n_x-3}]*[(mu)_4,(mu)_{n_y-3}]$. The reason for taking the extreme data values of x and y for these four knots is that, as is usual in data fitting, the fit cannot be expected to give satisfactory values outside the data region. If, nevertheless, the user requires values over a larger rectangle, this can be achieved by augmenting the data with two artificial data points (a,c,0) and (b,d,0) with zero weight, where [a,b]*[c,d] denotes the enlarged rectangle.

8.5. Outline of method used

First suitable knot sets are built up in stages (starting with no interior knots in the case of a cold start but with the knot set found in a previous call if a warm start is chosen). At each stage, a bicubic spline is fitted to the data by least-squares and (theta), the sum of squares of residuals, is computed. If (theta)>S, a new knot is added to one knot set or the other so as to reduce (theta) at the next stage. The new knot is located in an interval where the fit is particularly poor. Sooner or later, we find that (theta)<=S and at that point the knot sets are accepted. The routine then goes on to compute a spline which has these knot sets and which satisfies the full fitting criterion specified by (2) and (3). The theoretical solution has (theta)=S. The routine computes the spline by an iterative scheme which is ended when (theta)=S within a relative tolerance of 0.001. The main part of each iteration consists of a linear least-squares computation of special form, done in a similarly stable and efficient manner as in E02DAF. As there also, the minimal least-squares solution is computed wherever the linear system is found to be rank-deficient.

An exception occurs when the routine finds at the start that, even with no interior knots (N = 8), the least-squares spline already has its sum of squares of residuals <=S. In this case, since this spline (which is simply a bicubic polynomial) also has an optimal value for the smoothness measure (eta), namely zero, it is returned at once as the (trivial) solution. It will usually mean that S has been chosen too large.

For further details of the algorithm and its use see Dierckx [2].

8.6. Evaluation of computed spline

The values of the computed spline at the points (TX(r),TY(r)), for r = 1,2,...,N, may be obtained in the double precision array FF, of length at least N, by the following code:

```
      IFAIL = 0
      CALL E02DEF(N,NX,NY,TX,TY,LAMDA,MU,C,FF,WRK,IWRK,IFAIL)
```

where NX, NY, LAMDA, MU and C are the output parameters of E02DDF , WRK is a double precision workspace array of length at least NY-4, and IWRK is an integer workspace array of length at least NY-4.

To evaluate the computed spline on a KX by KY rectangular grid of points in the x-y plane, which is defined by the x co-ordinates stored in TX(q), for q=1,2,...,KX, and the y co-ordinates stored in TY(r), for r=1,2,...,KY, returning the results in the double precision array FG which is of length at least KX*KY, the following call may be used:

```
      IFAIL = 0
      CALL E02DFF(KX,KY,NX,NY,TX,TY,LAMDA,MU,C,FG,WRK,LWRK,
     *            IWRK,LIWRK,IFAIL)
```

where NX, NY, LAMDA, MU and C are the output parameters of E02DDF , WRK is a double precision workspace array of length at least LWRK = min(NWRK1,NWRK2), NWRK1 = KX*4+NX, NWRK2 = KY*4+NY, and IWRK is an integer workspace array of length at least LIWRK = KY + NY - 4 if NWRK1 >= NWRK2, or KX + NX - 4 otherwise. The result of the spline evaluated at grid point (q,r) is returned in element (KY*(q-1)+r) of the array FG.

9. Example

This example program reads in a value of M, followed by a set of M data points (x_r,y_r,f_r) and their weights w_r. It then calls E02DDF to compute a bicubic spline approximation for one specified value of S, and prints the values of the computed knots and B-spline coefficients. Finally it evaluates the spline at a small sample of points on a rectangular grid.

```
          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

                  E02DEF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          E02DEF calculates values of a bicubic spline from its B-spline
          representation.

          2. Specification

                 SUBROUTINE E02DEF (M, PX, PY, X, Y, LAMDA, MU, C, FF, WRK,
                1                   IWRK, IFAIL)
                 INTEGER          M, PX, PY, IWRK(PY-4), IFAIL
                 DOUBLE PRECISION X(M), Y(M), LAMDA(PX), MU(PY), C((PX-4)*
                1                 (PY-4)), FF(M), WRK(PY-4)

          3. Description
```

This routine calculates values of the bicubic spline s(x,y) at prescribed points (x_r,y_r), for r=1,2,...,m, from its augmented knot sets {(lambda)} and {(mu)} and from the coefficients c_{ij}, for i=1,2,...,PX-4; j=1,2,...,PY-4, in its B-spline representation

$$s(x,y)=\sum_{ij} c_{ij} M_i(x)N_j(y).$$

Here $M_i(x)$ and $N_j(y)$ denote normalised cubic B-splines, the former defined on the knots $(lambda)_i$ to $(lambda)_{i+4}$ and the latter on the knots $(mu)_j$ to $(mu)_{j+4}$.

This routine may be used to calculate values of a bicubic spline given in the form produced by E01DAF, E02DAF, E02DCF and E02DDF. It is derived from the routine B2VRE in Anthony et al [1].

[2] Cox M G (1978) The Numerical Evaluation of a Spline from its B-spline Representation. J. Inst. Math. Appl. 21 135--143.

5. Parameters

1: M -- INTEGER Input
On entry: m, the number of points at which values of the spline are required. Constraint: M >= 1.

2: PX -- INTEGER Input

3: PY -- INTEGER Input
On entry: PX and PY must specify the total number of knots associated with the variables x and y respectively. They are such that PX-8 and PY-8 are the corresponding numbers of interior knots. Constraint: PX >= 8 and PY >= 8.

4: X(M) -- DOUBLE PRECISION array Input

5: Y(M) -- DOUBLE PRECISION array Input

On entry: X and Y must contain x_r and y_r, for r=1,2,...,m, respectively. These are the co-ordinates of the points at which values of the spline are required. The order of the points is immaterial. Constraint: X and Y must satisfy

LAMDA(4) <= X(r) <= LAMDA(PX-3)

and

MU(4) <= Y(r) <= MU(PY-3), for r=1,2,...,m.

The spline representation is not valid outside these intervals.

6: LAMDA(PX) -- DOUBLE PRECISION array Input

7: MU(PY) -- DOUBLE PRECISION array Input
On entry: LAMDA and MU must contain the complete sets of knots {(lambda)} and {(mu)} associated with the x and y variables respectively. Constraint: the knots in each set must be in non-decreasing order, with LAMDA(PX-3) > LAMDA(4) and MU(PY-3) > MU(4).

8: C((PX-4)*(PY-4)) -- DOUBLE PRECISION array Input
On entry: C((PY-4)*(i-1)+j) must contain the coefficient c_{ij} described in Section 3, for i=1,2,...,PX-4; j=1,2,...,PY-4.

9: FF(M) -- DOUBLE PRECISION array Output
On exit: FF(r) contains the value of the spline at the point (x_r,y_r), for r=1,2,...,m.

10: WRK(PY-4) -- DOUBLE PRECISION array Workspace

11: IWRK(PY-4) -- INTEGER array Workspace

12: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

```
If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry M < 1,

     or       PY < 8,

     or       PX < 8.

IFAIL= 2
     On entry the knots in array LAMDA, or those in array MU, are
     not in non-decreasing order, or LAMDA(PX-3) <= LAMDA(4), or
     MU(PY-3) <= MU(4).

IFAIL= 3
     On entry at least one of the prescribed points (x ,y ) lies
                                                      r  r
     outside the rectangle defined by LAMDA(4), LAMDA(PX-3) and
     MU(4), MU(PY-3).

7. Accuracy

The method used to evaluate the B-splines is numerically stable,
in the sense that each computed value of s(x ,y ) can be regarded
                                            r  r
as the value that would have been obtained in exact arithmetic
from slightly perturbed B-spline coefficients. See Cox [2] for
details.

8. Further Comments

Computation time is approximately proportional to the number of
points, m, at which the evaluation is required.

9. Example

This program reads in knot sets LAMDA(1),..., LAMDA(PX) and MU(1)
,..., MU(PY), and a set of bicubic spline coefficients c  .
                                                        ij
Following these are a value for m and the co-ordinates (x ,y ),
                                                        r  r
for r=1,2,...,m, at which the spline is to be evaluated.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

          E02 -- Curve and Surface Fitting                           E02DFF
                  E02DFF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          E02DFF calculates values of a bicubic spline from its B-spline
          representation. The spline is evaluated at all points on a
          rectangular grid.

          2. Specification

                 SUBROUTINE E02DFF (MX, MY, PX, PY, X, Y, LAMDA, MU, C, FF,
                1                   WRK, LWRK, IWRK, LIWRK, IFAIL)
                 INTEGER          MX, MY, PX, PY, LWRK, IWRK(LIWRK), LIWRK,
                1                 IFAIL
                 DOUBLE PRECISION X(MX), Y(MY), LAMDA(PX), MU(PY), C((PX-4)*
                1                 (PY-4)), FF(MX*MY), WRK(LWRK)

          3. Description

          This routine calculates values of the bicubic spline s(x,y) on a
          rectangular grid of points in the x-y plane, from its augmented
          knot sets {(lambda)} and {(mu)} and from the coefficients c   ,
```

ij

for i=1,2,...,PX-4; j=1,2,...,PY-4, in its B-spline representation

$$s(x,y)=\sum_{ij} c_{ij} M_i(x)N_j(y).$$

Here $M_i(x)$ and $N_j(y)$ denote normalised cubic B-splines, the former defined on the knots $(\lambda)_i$ to $(\lambda)_{i+4}$ and the latter on the knots $(\mu)_j$ to $(\mu)_{j+4}$.

The points in the grid are defined by co-ordinates x_q, for $q=1,2,...,m_x$, along the x axis, and co-ordinates y_r, for $r=1,2,...,m_y$ along the y axis.

This routine may be used to calculate values of a bicubic spline given in the form produced by E01DAF, E02DAF, E02DCF and E02DDF. It is derived from the routine B2VRE in Anthony et al [1].

5. Parameters

1: MX -- INTEGER Input

2: MY -- INTEGER Input
On entry: MX and MY must specify m_x and m_y respectively, the number of points along the x and y axis that define the rectangular grid. Constraint: MX >= 1 and MY >= 1.

3: PX -- INTEGER Input

4: PY -- INTEGER Input
On entry: PX and PY must specify the total number of knots

associated with the variables x and y respectively. They are such that PX-8 and PY-8 are the corresponding numbers of interior knots. Constraint: PX >= 8 and PY >= 8.

5: X(MX) -- DOUBLE PRECISION array Input

6: Y(MY) -- DOUBLE PRECISION array Input
On entry: X and Y must contain x_q, for q=1,2,...,m_x, and y_r, for r=1,2,...,m_y, respectively. These are the x and y co-ordinates that define the rectangular grid of points at which values of the spline are required. Constraint: X and Y must satisfy

LAMDA(4) <= X(q) < X(q+1) <= LAMDA(PX-3), for q=1,2,...,m_x-1

and

MU(4) <= Y(r) < Y(r+1) <= MU(PY-3), for r=1,2,...,m_y-1.

The spline representation is not valid outside these intervals.

7: LAMDA(PX) -- DOUBLE PRECISION array Input

8: MU(PY) -- DOUBLE PRECISION array Input
On entry: LAMDA and MU must contain the complete sets of knots {(lambda)} and {(mu)} associated with the x and y variables respectively. Constraint: the knots in each set must be in non-decreasing order, with LAMDA(PX-3) > LAMDA(4) and MU(PY-3) > MU(4).

9: C((PX-4)*(PY-4)) -- DOUBLE PRECISION array Input
On entry: C((PY-4)*(i-1)+j) must contain the coefficient c_{ij} described in Section 3, for i=1,2,...,PX-4; j=1,2,...,PY-4.

10: FF(MX*MY) -- DOUBLE PRECISION array Output
On exit: FF(MY*(q-1)+r) contains the value of the spline at the point (x_q,y_r), for q=1,2,...,m_x; r=1,2,...,m_y.

11: WRK(LWRK) -- DOUBLE PRECISION array Workspace

12: LWRK -- INTEGER Input
On entry:
the dimension of the array WRK as declared in the

```
     (sub)program from which E02DFF is called.
     Constraint: LWRK >= min(NWRK1,NWRK2), where NWRK1=4*MX+PX,
     NWRK2=4*MY+PY.

13:  IWRK(LIWRK) -- INTEGER array                      Workspace

14:  LIWRK -- INTEGER                                      Input
     On entry:
     the dimension of the array IWRK as declared in the
     (sub)program from which E02DFF is called.
     Constraint: LIWRK >= MY + PY - 4 if NWRK1 > NWRK2, or MX +
     PX - 4 otherwise, where NWRK1 and NWRK2 are as defined in
     the description of argument LWRK.

15:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry MX < 1,

     or       MY < 1,

     or       PY < 8,

     or       PX < 8.

IFAIL= 2
     On entry LWRK is too small,

     or       LIWRK is too small.

IFAIL= 3
     On entry the knots in array LAMDA, or those in array MU, are
     not in non-decreasing order, or LAMDA(PX-3) <= LAMDA(4), or
     MU(PY-3) <= MU(4).

IFAIL= 4
     On entry the restriction LAMDA(4) <= X(1) <... < X(MX) <=
              LAMDA(PX-3), or the restriction MU(4) <= Y(1) <... < Y(MY)
              <= MU(PY-3), is violated.

          7. Accuracy

          The method used to evaluate the B-splines is numerically stable,
          in the sense that each computed value of s(x ,y ) can be regarded
                                                      r  r
          as the value that would have been obtained in exact arithmetic
          from slightly perturbed B-spline coefficients. See Cox [2] for
          details.

          8. Further Comments

          Computation time is approximately proportional to m m +4(m +m ).
                                                             x y    x  y

          9. Example

          This program reads in knot sets LAMDA(1),..., LAMDA(PX) and MU(1)
          ,..., MU(PY), and a set of bicubic spline coefficients c  .
                                                                  ij
          Following these are values for m  and the x co-ordinates x , for
                                          x                         q
          q=1,2,...,m , and values for m  and the y co-ordinates y , for
                     x                  y                        r
          r=1,2,...,m , defining the grid of points on which the spline is
                     y
          to be evaluated.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

     E02 -- Curve and Surface Fitting                           E02GAF
             E02GAF -- NAG Foundation Library Routine Document

     Note: Before using this routine, please read the Users' Note for
     your implementation to check implementation-dependent details.
     The symbol (*) after a NAG routine name denotes a routine that is
     not included in the Foundation Library.

     1. Purpose

     E02GAF calculates an l  solution to an over-determined system of
                           1
     linear equations.

     2. Specification

            SUBROUTINE E02GAF (M, A, LA, B, NPLUS2, TOLER, X, RESID,
           1                   IRANK, ITER, IWORK, IFAIL)
            INTEGER          M, LA, NPLUS2, IRANK, ITER, IWORK(M),
           1                 IFAIL
            DOUBLE PRECISION A(LA,NPLUS2), B(M), TOLER, X(NPLUS2),
           1                 RESID

     3. Description

     Given a matrix A with m rows and n columns (m>=n) and a vector b
     with m elements, the routine calculates an l  solution to the
                                                 1
     over-determined system of equations

                                  Ax=b.

     That is to say, it calculates a vector x, with n elements, which
     minimizes the l -norm (the sum of the absolute values) of the
                    1
     residuals

                                   m
                                   --
                             r(x)= >  |r |,
                                   --   i
                                   i=1
```

where the residuals r_i are given by

$$r_i=b_i-\sum_{j=1}^{n} a_{ij}x_j, \quad i=1,2,\ldots,m.$$

Here a_{ij} is the element in row i and column j of A, b_i is the ith element of b and x_j the jth element of x. The matrix A need not be of full rank.

Typically in applications to data fitting, data consisting of m points with co-ordinates (t_i,y_i) are to be approximated in the l_1-norm by a linear combination of known functions $\phi_j(t)$,

$$\alpha_1\phi_1(t)+\alpha_2\phi_2(t)+\ldots+\alpha_n\phi_n(t).$$

This is equivalent to fitting an l_1 solution to the over-determined system of equations

$$\sum_{j=1}^{n}\phi_j(t_i)\alpha_j=y_i, \quad i=1,2,\ldots,m.$$

Thus if, for each value of i and j, the element a_{ij} of the matrix A in the previous paragraph is set equal to the value of $\phi_j(t_i)$ and b_i is set equal to y_i, the solution vector x will contain the required values of the α_j. Note that the independent variable t above can, instead, be a vector of several independent variables (this includes the case where each ϕ_i is a function of a different variable, or set of variables).

The algorithm is a modification of the simplex method of linear programming applied to the primal formulation of the l_1 problem (see Barrodale and Roberts [1] and [2]). The modification allows several neighbouring simplex vertices to be passed through in a single iteration, providing a substantial improvement in efficiency.

5. Parameters

```
 1:  M -- INTEGER                                          Input
     On entry: the number of equations, m (the number of rows of
     the matrix A). Constraint: M >= n >= 1.

 2:  A(LA,NPLUS2) -- DOUBLE PRECISION array         Input/Output
     On entry: A(i,j) must contain a   , the element in the ith
                                    ij
     row and jth column of the matrix A, for i=1,2,...,m and
     j=1,2,...,n. The remaining elements need not be set. On
     exit: A contains the last simplex tableau generated by the
     simplex method.

 3:  LA -- INTEGER                                         Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which E02GAF is called.
     Constraint: LA >= M + 2.

 4:  B(M) -- DOUBLE PRECISION array                 Input/Output
     On entry: b , the ith element of the vector b, for
                i
     i=1,2,...,m. On exit: the ith residual r  corresponding to
                                             i
     the solution vector x, for i=1,2,...,m.

 5:  NPLUS2 -- INTEGER                                     Input
     On entry: n+2, where n is the number of unknowns (the
     number of columns of the matrix A). Constraint: 3 <= NPLUS2
     <= M + 2.

 6:  TOLER -- DOUBLE PRECISION                             Input
     On entry: a non-negative value. In general TOLER specifies
     a threshold below which numbers are regarded as zero. The
                                                  2/3
     recommended threshold value is (epsilon)    where (epsilon)
     is the machine precision. The recommended value can be
     computed within the routine by setting TOLER to zero. If
     premature termination occurs a larger value for TOLER may
     result in a valid solution. Suggested value: 0.0.

 7:  X(NPLUS2) -- DOUBLE PRECISION array                  Output
     On exit: X(j) contains the jth element of the solution
     vector x, for j=1,2,...,n. The elements X(n+1) and X(n+2)
     are unused.

 8:  RESID -- DOUBLE PRECISION                            Output
     On exit: the sum of the absolute values of the residuals
     for the solution vector x.

 9:  IRANK -- INTEGER                                     Output
     On exit: the computed rank of the matrix A.

10:  ITER -- INTEGER                                      Output
     On exit: the number of iterations taken by the simplex
     method.

11:  IWORK(M) -- INTEGER array                         Workspace

12:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     An optimal solution has been obtained but this may not be
     unique.

IFAIL= 2
     The calculations have terminated prematurely due to rounding
     errors. Experiment with larger values of TOLER or try
     scaling the columns of the matrix (see Section 8).

IFAIL= 3
     On entry NPLUS2 < 3,
```

or NPLUS2 > M + 2,

or LA < M + 2.

7. Accuracy

Experience suggests that the computational accuracy of the solution x is comparable with the accuracy that could be obtained by applying Gaussian elimination with partial pivoting to the n equations satisfied by this algorithm (i.e., those equations with zero residuals). The accuracy therefore varies with the conditioning of the problem, but has been found generally very satisfactory in practice.

8. Further Comments

The effects of m and n on the time and on the number of iterations in the Simplex Method vary from problem to problem, but typically the number of iterations is a small multiple of n and the total time taken by the routine is approximately proportional to mn^2.

It is recommended that, before the routine is entered, the columns of the matrix A are scaled so that the largest element in each column is of the order of unity. This should improve the conditioning of the matrix, and also enable the parameter TOLER to perform its correct function. The solution x obtained will then, of course, relate to the scaled form of the matrix. Thus if the scaling is such that, for each j=1,2,...,n, the elements of the jth column are multiplied by the constant k_j, the element x_j of the solution vector x must be multiplied by k_j if it is desired to recover the solution corresponding to the original matrix A.

9. Example

Suppose we wish to approximate a set of data by a curve of the form

$$y=Ke^t+Le^{-t}+M$$

where K, L and M are unknown. Given values y_i at 5 points t_i we may form the over-determined set of equations for K, L and M

x -x

```
                         i     i
                        e  K+e   L+M=y ,  i=1,2,...,5.
                                      i

          E02GAF is used to solve these in the l  sense.
                                                1

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

                  E02ZAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          E02ZAF sorts two-dimensional data into rectangular panels.

          2. Specification

                 SUBROUTINE E02ZAF (PX, PY, LAMDA, MU, M, X, Y, POINT,
                1                   NPOINT, ADRES, NADRES, IFAIL)
```

```
       INTEGER         PX, PY, M, POINT(NPOINT), NPOINT, ADRES
      1                (NADRES), NADRES, IFAIL
       DOUBLE PRECISION LAMDA(PX), MU(PY), X(M), Y(M)
```

3. Description

A set of m data points with rectangular Cartesian co-ordinates x_r,y_r are sorted into panels defined by lines parallel to the y and x axes. The intercepts of these lines on the x and y axes are given in LAMDA(i), for i=5,6,...,PX-4 and MU(j), for j=5,6,...,PY-4, respectively. The subroutine orders the data so that all points in a panel occur before data in succeeding panels, where the panels are numbered from bottom to top and then left to right, with the usual arrangement of axes, as shown in the diagram. Within a panel the points maintain their original order.

Please see figure in printed Reference Manual

A data point lying exactly on one or more panel sides is taken to be in the highest-numbered panel adjacent to the point. The subroutine does not physically rearrange the data, but provides the array POINT which contains a linked list for each panel, pointing to the data in that panel. The total number of panels is (PX-7)*(PY-7).

4. References

None.

5. Parameters

1: PX -- INTEGER Input

2: PY -- INTEGER Input

On entry: PX and PY must specify eight more than the number of intercepts on the x axis and y axis, respectively. Constraint: PX >= 8 and PY >= 8.

3: LAMDA(PX) -- DOUBLE PRECISION array Input
On entry: LAMDA(5) to LAMDA(PX-4) must contain, in non-decreasing order, the intercepts on the x axis of the sides of the panels parallel to the y axis.

4: MU(PY) -- DOUBLE PRECISION array Input
On entry: MU(5) to MU(PY-4) must contain, in non-decreasing order, the intercepts on the y axis of the sides of the panels parallel to the x axis.

```
 5:  M -- INTEGER                                         Input
     On entry: the number m of data points.

 6:  X(M) -- DOUBLE PRECISION array                       Input

 7:  Y(M) -- DOUBLE PRECISION array                       Input
     On entry: the co-ordinates of the rth data point (x ,y ),
                                                        r  r
     for r=1,2,...,m.

 8:  POINT(NPOINT) -- INTEGER array                      Output
     On exit: for i = 1,2,...,NADRES, POINT(m+i) = I1 is the
     index of the first point in panel i, POINT(I1) = I2 is the
     index of the second point in panel i and so on.

     POINT(IN) = 0 indicates that X(IN),Y(IN) was the last point
     in the panel.

     The co-ordinates of points in panel i can be accessed in
     turn by means of the following instructions:
        IN = M + I
     10 IN = POINT(IN)
        IF (IN.EQ. 0) GOTO 20
        XI = X(IN)
        YI = Y(IN)
        .
        .
        .
        GOTO 10
     20...

 9:  NPOINT -- INTEGER                                    Input
     On entry:
     the dimension of the array POINT as declared in the
     (sub)program from which E02ZAF is called.
     Constraint: NPOINT >= M + (PX-7)*(PY-7).

10:  ADRES(NADRES) -- INTEGER array                   Workspace

11:  NADRES -- INTEGER                                    Input
     On entry: the value (PX-7)*(PY-7), the number of panels
     into which the (x,y) plane is divided.

12:  IFAIL -- INTEGER                              Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
               Section 6).

          6. Error Indicators and Warnings

          Errors detected by the routine:

          If on entry IFAIL = 0 or -1, explanatory error messages are
          output on the current error message unit (as defined by X04AAF).

          IFAIL= 1
               The intercepts in the array LAMDA, or in the array MU, are
               not in non-decreasing order.

          IFAIL= 2
               On entry PX < 8,

               or       PY < 8,

               or       M <= 0,

               or       NADRES /= (PX-7)*(PY-7),

               or       NPOINT < M + (PX-7)*(PY-7).

          7. Accuracy

          Not applicable.

          8. Further Comments

          The time taken by this routine is approximately proportional to
          m*log(NADRES).

          This subroutine was written to sort two dimensional data in the
          manner required by routines E02DAF and E02DBF(*). The first 9
          parameters of E02ZAF are the same as the parameters in E02DAF and
          E02DBF(*) which have the same name.

          9. Example

          This example program reads in data points and the intercepts of
          the panel sides on the x and y axes; it calls E02ZAF to set up
          the index array POINT; and finally it prints the data points in
          panel order.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

1. Scope of the Chapter

An optimization problem involves minimizing a function (called the objective function) of several variables, possibly subject to restrictions on the values of the variables defined by a set of constraint functions. The routines in the NAG Foundation Library are concerned with function minimization only, since the problem of maximizing a given function can be transformed into a minimization problem simply by multiplying the function by -1.

This introduction is only a brief guide to the subject of optimization designed for the casual user. Anyone with a difficult or protracted problem to solve will find it beneficial to consult a more detailed text, such as Gill et al [5] or Fletcher [3].

Readers who are unfamiliar with the mathematics of the subject may find some sections difficult at first reading; if so, they should concentrate on Sections 2.1, 2.2, 2.5, 2.6 and 3.

2. Background to the Problems

2.1. Types of Optimization Problems

Solution of optimization problems by a single, all-purpose, method is cumbersome and inefficient. Optimization problems are therefore classified into particular categories, where each category is defined by the properties of the objective and constraint functions, as illustrated by some examples below.

Properties of Objective Function	Properties of Constraints
Nonlinear	Nonlinear
Sums of squares of nonlinear functions	Sparse linear
Quadratic	Linear
Sums of squares of linear functions	Bounds
Linear	None

For instance, a specific problem category involves the minimization of a nonlinear objective function subject to bounds on the variables. In the following sections we define the particular categories of problems that can be solved by routines contained in this Chapter.

2.1.1. Unconstrained minimization

In unconstrained minimization problems there are no constraints on the variables. The problem can be stated mathematically as follows:

$$\operatorname*{minimize}_{x} F(x)$$

where x is in R^n, that is, $x=(x_1,x_2,...,x_n)^T$.

2.1.2. Nonlinear least-squares problems

Special consideration is given to the problem for which the function to be minimized can be expressed as a sum of squared functions. The least-squares problem can be stated mathematically as follows:

$$\operatorname*{minimize}_{x} \left\{ f^T f = \sum_{i=1}^{m} f_i^2(x) \right\}, \quad x \text{ is in } R^n$$

where the ith element of the m-vector f is the function $f_i(x)$.

2.1.3. Minimization subject to bounds on the variables

These problems differ from the unconstrained problem in that at least one of the variables is subject to a simple restriction on its value, e.g.$x_5 <=10$, but no constraints of a more general form are present.

The problem can be stated mathematically as follows:

$$\operatorname*{minimize}_{x} F(x), \quad x \text{ is in } R^n$$

subject to $l_i <=x_i <=u_i$, i=1,2,...,n.

This format assumes that upper and lower bounds exist on all the variables. By conceptually allowing u_i=infty and l_i=-infty all the variables need not be restricted.

2.1.4. Minimization subject to linear constraints

A general linear constraint is defined as a constraint function that is linear in more than one of the variables, e.g. $3x_1+2x_2>=4$ The various types of linear constraint are reflected in the following mathematical statement of the problem:

$$\underset{x}{\text{minimize}}\ F(x),\quad x \text{ is in } R^n$$

subject to the

equality constraints:	$a_i^Tx=b_i$	$i=1,2,\ldots,m_1$;
inequality constraints:	$a_i^Tx>=b_i$	$i=m_1+1,m_1+2,\ldots,m_2$;
	$a_i^Tx<=b_i$	$i=m_2+1,m_2+2,\ldots,m_3$;
range constraints:	$s_j<=a_i^Tx<=t_j$	$i=m_3+1,m_3+2,\ldots,m_4$; $j=1,2,\ldots,m_4-m_3$;
bounds constraints:	$l_i<=x_i<=u_i$	$i=1,2,\ldots,n$

where each a_i is a vector of length n; b_i, s_j and t_j are constant scalars; and any of the categories may be empty.

Although the bounds on x_i could be included in the definition of general linear constraints, we prefer to distinguish between them for reasons of computational efficiency.

If F(x) is a linear function, the linearly-constrained problem is termed a linear programming problem (LP problem); if $F(x)$ is a quadratic function, the problem is termed a quadratic programming problem (QP problem). For further discussion of LP and QP problems, including the dual formulation of such problems, see Dantzig [2].

2.1.5. Minimization subject to nonlinear constraints

A problem is included in this category if at least one constraint function is nonlinear, e.g. $x_1^2+x_3+x_4-2>=0$. The mathematical statement of the problem is identical to that for the linearly-constrained case, except for the addition of the following constraints:

equality constraints:	$c_i(x)=0$	$i=1,2,...,m_5$;
inequality constraints:	$c_i(x)>=0$	$i=m_5+1,m_5+2,...,m_6$;
range constraints:	$v_j<=c_i(x)<=w_j$	$i=m_6+1,m_6+2,...,m_7$, $j=1,2,...,m_7-m_6$

where each c_i is a nonlinear function; v_j and w_j are constant scalars; and any category may be empty. Note that we do not include a separate category for constraints of the form $c_i(x)<=0$, since this is equivalent to $-c_i(x)>=0$.

2.2. Geometric Representation and Terminology

To illustrate the nature of optimization problems it is useful to consider the following example in two dimensions

$$F(x)=e^{x_1}(4x_1^2+2x_2^2+4x_1x_2+2x_2+1).$$

(This function is used as the example function in the documentation for the unconstrained routines.)

Figure 1

Please see figure in printed Reference Manual

Figure 1 is a contour diagram of $F(x)$. The contours labelled $F_0, F_1, \ldots, F_4$ are isovalue contours, or lines along which the function $F(x)$ takes specific constant values. The point x^* is a local unconstrained minimum, that is, the value of $F(x^*)$ is less than at all the neighbouring points. A function may have several such minima. The lowest of the local minima is termed a global minimum. In the problem illustrated in Figure 1, x^* is the only local minimum. The point x is said to be a saddle point because it is a minimum along the line AB, but a maximum along CD.

If we add the constraint $x_1 >= 0$ to the problem of minimizing $F(x)$, the solution remains unaltered. In Figure 1 this constraint is represented by the straight line passing through $x_1 = 0$, and the shading on the line indicates the unacceptable region. The region in R^n satisfying the constraints of an optimization problem is termed the feasible region. A point satisfying the constraints is defined as a feasible point.

If we add the nonlinear constraint $x_1 + x_2 - x_1 x_2 - 1.5 >= 0$, represented by the curved shaded line in Figure 1, then x^* is not a feasible point. The solution of the new constrained problem is $\hat{x}$, the feasible point with the smallest function value.

2.2.1. Gradient vector

The vector of first partial derivatives of $F(x)$ is called the gradient vector, and is denoted by $g(x)$, i.e.,

$$g(x) = \left[\frac{\partial F(x)}{\partial x_1}, \frac{\partial F(x)}{\partial x_2}, \ldots, \frac{\partial F(x)}{\partial x_n} \right]^T .$$

For the function illustrated in Figure 1,

[x]

$$g(x)=\begin{bmatrix} F(x)+e^{x_1}(8x_1+4x_2) \\ e^{x_1}(4x_2+4x_1+2) \end{bmatrix}.$$

The gradient vector is of importance in optimization because it must be zero at an unconstrained minimum of any function with continuous first derivatives.

2.2.2. Hessian matrix

The matrix of second partial derivatives of a function is termed its Hessian matrix. The Hessian matrix of F(x) is denoted by G(x) and its (i,j)th element is given by $\partial^2 F(x)/\partial x_i \partial x_j$. If F(x) has continuous second derivatives, then G(x) must be positive semi-definite at any unconstrained minimum of F.

2.2.3. Jacobian matrix; matrix of constraint normals

In nonlinear least-squares problems, the matrix of first partial derivatives of the vector-valued function f(x) is termed the Jacobian matrix of f(x) and its (i,j)th component is $\partial f_i/\partial x_j$.

The vector of first partial derivatives of the constraint $c_i(x)$ is denoted by

$$a_i(x)=\left[\frac{\partial c_i(x)}{\partial x_1},\ldots,\frac{\partial c_i(x)}{\partial x_n}\right]^T .$$

At a point, $\hat{x}$, the vector $a_i(\hat{x})$ is orthogonal (normal) to the isovalue contour of $c_i(x)$ passing through $\hat{x}$; this relationship is illustrated for a two-dimensional function in Figure 2.

Figure 2
Please see figure in printed Reference Manual

The matrix whose columns are the vectors $\{a_i\}$ is termed the matrix of constraint normals. Note that if $c_i(x)$ is a linear constraint involving $a_i^T x$, then its vector of first partial derivatives is simply the vector a_i.

2.3. Sufficient Conditions for a Solution

All nonlinear functions will be assumed to have continuous second derivatives in the neighbourhood of the solution.

2.3.1. Unconstrained minimization

The following conditions are sufficient for the point x^* to be an unconstrained local minimum of $F(x)$:

(i) $|||g(x^*)|||=0$; and

(ii) $G(x^*)$ is positive-definite,

where $|||g|||$ denotes the Euclidean length of g.

2.3.2. Minimization subject to bounds on the variables

At the solution of a bounds-constrained problem, variables which are not on their bounds are termed free variables. If it is known in advance which variables are on their bounds at the solution, the problem can be solved as an unconstrained problem in just the free variables; thus, the sufficient conditions for a solution are similar to those for the unconstrained case, applied only to the free variables.

Sufficient conditions for a feasible point x^* to be the solution of a bound-constrained problem are as follows:

(i) $|||g(x^*)|||=0$; and

(ii) $G(x^*)$ is positive-definite; and

(iii) $g_j(x^*)<0, x_j=u_j$; $g_j(x^*)>0, x_j=l_j$,

where g(x) is the gradient of F(x) with respect to the free

variables, and G(x) is the Hessian matrix of F(x) with respect to the free variables. The extra condition (iii) ensures that F(x) cannot be reduced by moving off one or more of the bounds.

2.3.3. Linearly-constrained minimization

For the sake of simplicity, the following description does not include a specific treatment of bounds or range constraints, since the results for general linear inequality constraints can be applied directly to these cases.

At a solution x^*, of a linearly-constrained problem, the constraints which hold as equalities are called the active or binding constraints. Assume that there are t active constraints at the solution x^*, and let $\hat{A}$ denote the matrix whose columns are the columns of A corresponding to the active constraints, with $\hat{b}$ the vector similarly obtained from b; then

$$\hat{A}^T x^* = \hat{b}.$$

The matrix Z is defined as an n by (n-t) matrix satisfying:

$$\hat{A}^T Z=0; \quad Z^T Z=I.$$

The columns of Z form an orthogonal basis for the set of vectors orthogonal to the columns of $\hat{A}$.

Define

$g_z(x)=Z^T g(x)$, the projected gradient vector of F(x);

$G_z(x)=Z^T G(x)Z$, the projected Hessian matrix of F(x).

$_z$

At the solution of a linearly-constrained problem, the projected gradient vector must be zero, which implies that the gradient vector $g(x^*)$ can be written as a linear combination of the columns of $\hat{A}$, i.e., $g(x^*)=\sum_{i=1}^{t}\lambda_i\hat{a}_i=\hat{A}\lambda$. The scalar λ_i is defined as the Lagrange multiplier corresponding to the ith active constraint. A simple interpretation of the ith Lagrange multiplier is that it gives the gradient of $F(x)$ along the ith active constraint normal; a convenient definition of the Lagrange multiplier vector (although not a recommended method for computation) is:

$$\lambda=(\hat{A}^T\hat{A})^{-1}\hat{A}^T g(x^*).$$

Sufficient conditions for x^* to be the solution of a linearly-constrained problem are:

(i) x^* is feasible, and $\hat{A}^T x^*=\hat{b}$; and

(ii) $\|g_z(x^*)\|=0$, or equivalently, $g(x^*)=\hat{A}\lambda$; and

(iii) $G_z(x^*)$ is positive-definite; and

(iv) $\lambda_i>0$ if λ_i corresponds to a constraint $\hat{a}_i^T x^*\geq\hat{b}_i$;

$\lambda_i<0$ if λ_i corresponds to a constraint $\hat{a}_i^T x^*\leq\hat{b}_i$.

The sign of λ_i is immaterial for equality constraints, which by definition are always active.

2.3.4. Nonlinearly-constrained minimization

For nonlinearly-constrained problems, much of the terminology is defined exactly as in the linearly-constrained case. The set of active constraints at x again means the set of constraints that hold as equalities at x, with corresponding definitions of $\hat{c}$ and $\hat{A}$: the vector $\hat{c}(x)$ contains the active constraint functions, and the columns of $\hat{A}(x)$ are the gradient vectors of the active constraints. As before, Z is defined in terms of $\hat{A}(x)$ as a matrix such that:

$$\hat{A}^T Z=0; \quad Z^T Z=I$$

where the dependence on x has been suppressed for compactness.

The projected gradient vector $g_z(x)$ is the vector $Z^T g(x)$. At the solution x^* of a nonlinearly-constrained problem, the projected gradient must be zero, which implies the existence of Lagrange multipliers corresponding to the active constraints, i.e., $g(x^*)=\hat{A}(x^*)(\lambda)$.

The Lagrangian function is given by:

$$L(x,(\lambda))=F(x)-(\lambda)^T\hat{c}(x).$$

We define $g_L(x)$ as the gradient of the Lagrangian function; $G_L(x)$ as its Hessian matrix, and $\hat{G}_L(x)$ as its projected Hessian matrix, i.e., $\hat{G}_L=Z^T G_L Z$.

*

Sufficient conditions for x to be a solution of nonlinearly-constrained problem are:

(i) x^* is feasible, and $\hat{c}(x^*)=0$; and

(ii) $|||g_z(x^*)|||=0$, or, equivalently, $g(x^*)=\hat{A}(x^*)(\text{lambda})$; and

(iii) $\hat{G}_L(x^*)$ is positive-definite; and

(iv) $(\text{lambda})_i>0$ if $(\text{lambda})_i$ corresponds to a constraint of the form $\hat{c}_i>=0$; the sign of $(\text{lambda})_i$ is immaterial for an equality constraint.

Note that condition (ii) implies that the projected gradient of the Lagrangian function must also be zero at x^*, since the application of Z^T annihilates the matrix $\hat{A}(x^*)$.

2.4. Background to Optimization Methods

All the algorithms contained in this Chapter generate an iterative sequence $\{x^{(k)}\}$ that converges to the solution x^* in the limit, except for some special problem categories (i.e., linear and quadratic programming). To terminate computation of the sequence, a convergence test is performed to determine whether the current estimate of the solution is an adequate approximation. The convergence tests are discussed in Section 2.6

Most of the methods construct a sequence $\{x^{(k)}\}$ satisfying:

$$x^{(k+1)}=x^{(k)}+(\text{alpha})^{(k)}p^{(k)},$$

where the vector $p^{(k)}$ is termed the direction of search, and $(\text{alpha})^{(k)}$ is the steplength. The steplength $(\text{alpha})^{(k)}$ is chosen so that $F(x^{(k+1)})<F(x^{(k)})$.

2.4.1. Methods for unconstrained optimization

The distinctions among methods arise primarily from the need to use varying levels of information about derivatives of F(x) in defining the search direction. We describe three basic approaches to unconstrained problems, which may be extended to other problem categories. Since a full description of the methods would fill several volumes, the discussion here can do little more than allude to the processes involved, and direct the reader to other sources for a full explanation.

(a) Newton-type Methods (Modified Newton Methods)

Newton-type methods use the Hessian matrix $G(x^{(k)})$, or a finite difference approximation to $G(x^{(k)})$, to define the search direction. The routines in the Library either require a subroutine that computes the elements of $G(x^{(k)})$, or they approximate $G(x^{(k)})$ by finite differences.

Newton-type methods are the most powerful methods available for general problems and will find the minimum of a quadratic function in one iteration. See Sections 4.4. and 4.5.1. of Gill et al [5].

(b) Quasi-Newton Methods

Quasi-Newton methods approximate the Hessian $G(x^{(k)})$ by a matrix $B^{(k)}$ which is modified at each iteration to include information obtained about the curvature of F along the latest search direction. Although not as robust as Newton-type methods, quasi-Newton methods can be more efficient because $G(x^{(k)})$ is not computed, or approximated by finite-differences. Quasi-Newton methods minimize a quadratic function in n iterations. See Section 4.5.2 of Gill et al [5].

(c) Conjugate-Gradient Methods

Unlike Newton-type and quasi-Newton methods, conjugate gradient methods do not require the storage of an n by n matrix and so are ideally suited to solve large problems.

Conjugate-gradient type methods are not usually as reliable or efficient as Newton-type, or quasi-Newton methods. See Section 4.8.3 of Gill et al [5].

2.4.2. Methods for nonlinear least-squares problems

These methods are similar to those for unconstrained optimization, but exploit the special structure of the Hessian matrix to give improved computational efficiency.

Since

$$F(x)=\sum_{i=1}^{m} f_i^2(x)$$

the Hessian matrix $G(x)$ is of the form

$$G(x)=2[J(x)^T J(x)+\sum_{i=1}^{m} f_i(x)G_i(x)],$$

where $J(x)$ is the Jacobian matrix of $f(x)$, and $G_i(x)$ is the Hessian matrix of $f_i(x)$.

In the neighbourhood of the solution, $|||f(x)|||$ is often small compared to $|||J(x)^T J(x)|||$ (for example, when $f(x)$ represents the goodness of fit of a nonlinear model to observed data). In such cases, $2J(x)^T J(x)$ may be an adequate approximation to $G(x)$, thereby avoiding the need to compute or approximate second derivatives of $\{f_i(x)\}$. See Section 4.7 of Gill et al [5].

2.4.3. Methods for handling constraints

Bounds on the variables are dealt with by fixing some of the variables on their bounds and adjusting the remaining free variables to minimize the function. By examining estimates of the Lagrange multipliers it is possible to adjust the set of variables fixed on their bounds so that eventually the bounds active at the solution should be correctly identified. This type of method is called an active set method. One feature of such methods is that, given an initial feasible point, all approximations $x^{(k)}$ are feasible. This approach can be extended to general linear constraints. At a point, x, the set of constraints which hold as equalities being used to predict, or approximate, the set of active constraints is called the working set.

Nonlinear constraints are more difficult to handle. If at all possible, it is usually beneficial to avoid including nonlinear constraints during the formulation of the problem. The methods currently implemented in the Library handle nonlinearly constrained problems either by transforming them into a sequence of bound constraint problems, or by transforming them into a sequence of quadratic programming problems. A feature of almost all methods for nonlinear constraints is that $x^{(k)}$ is not guaranteed to be feasible except in the limit, and this is certainly true of the routines currently in the Library. See Chapter 6, particularly Section 6.4 and Section 6.5 of Gill et al [5].

Anyone interested in a detailed description of methods for optimization should consult the references.

2.5. Scaling

Scaling (in a broadly defined sense) often has a significant influence on the performance of optimization methods. Since convergence tolerances and other criteria are necessarily based on an implicit definition of 'small' and 'large', problems with unusual or unbalanced scaling may cause difficulties for some algorithms. Nonetheless, there are currently no scaling routines in the Library, although the position is under constant review. In light of the present state of the art, it is considered that sensible scaling by the user is likely to be more effective than any automatic routine. The following sections present some general comments on problem scaling.

2.5.1. Transformation of variables

One method of scaling is to transform the variables from their original representation, which may reflect the physical nature of the problem, to variables that have certain desirable properties in terms of optimization. It is generally helpful for the following conditions to be satisfied:

(i) the variables are all of similar magnitude in the region of interest;

(ii) a fixed change in any of the variables results in similar changes in $F(x)$. Ideally, a unit change in any variable produces a unit change in $F(x)$;

(iii) the variables are transformed so as to avoid cancellation error in the evaluation of $F(x)$.

Normally, users should restrict themselves to linear transformations of variables, although occasionally nonlinear transformations are possible. The most common such transformation (and often the most appropriate) is of the form

$$x_{new}=Dx_{old},$$

where D is a diagonal matrix with constant coefficients. Our experience suggests that more use should be made of the transformation

$$x_{new}=Dx_{old}+v,$$

where v is a constant vector.

Consider, for example, a problem in which the variable x_3 represents the position of the peak of a Gaussian curve to be fitted to data for which the extreme values are 150 and 170; therefore x_3 is known to lie in the range 150--170. One possible

scaling would be to define a new variable x_3, given by

$$x_3 = \frac{x_3}{170}.$$

A better transformation, however, is given by defining x_3 as

$$x = \frac{x_3-160}{}.$$

3   10

Frequently, an improvement in the accuracy of evaluation of F(x) can result if the variables are scaled before the routines to evaluate F(x) are coded. For instance, in the above problem just mentioned of Gaussian curve fitting, x_3 may always occur in terms of the form (x_3-x_m), where x_m is a constant representing the mean peak position.

2.5.2. Scaling the objective function

The objective function has already been mentioned in the discussion of scaling the variables. The solution of a given problem is unaltered if F(x) is multiplied by a positive constant, or if a constant value is added to F(x). It is generally preferable for the objective function to be of the order of unity in the region of interest; thus, if in the original formulation F(x) is always of the order of 10^{+5} (say), then the value of F(x) should be multiplied by 10^{-5} when evaluating the function within the optimization routines. If a constant is added or subtracted in the computation of F(x), usually it should be omitted - i.e., it is better to formulate F(x) as $x_1^2+x_2^2$ rather than as $x_1^2+x_2^2+1000$ or even $x_1^2+x_2^2+1$. The inclusion of such a constant in the calculation of F(x) can result in a loss of significant figures.

2.5.3. Scaling the constraints

The solution of a nonlinearly-constrained problem is unaltered if the ith constraint is multiplied by a positive weight w_i. At the approximation of the solution determined by a Library routine, the active constraints will not be satisfied exactly, but will have 'small' values (for example, $c_1=10^{-8}$, $c_2=10^{-6}$, etc.). In general, this discrepancy will be minimized if the constraints are weighted so that a unit change in x produces a similar change in each constraint.

A second reason for introducing weights is related to the effect of the size of the constraints on the Lagrange multiplier estimates and, consequently, on the active set strategy. Additional discussion is given in Gill et al [5].

2.6. Analysis of Computed Results

2.6.1. Convergence criteria

The convergence criteria inevitably vary from routine to routine, since in some cases more information is available to be checked (for example, is the Hessian matrix positive-definite?), and different checks need to be made for different problem categories (for example, in constrained minimization it is necessary to verify whether a trial solution is feasible). Nonetheless, the underlying principles of the various criteria are the same; in non-mathematical terms, they are:

(i) is the sequence $\{x^{(k)}\}$ converging?

(ii) is the sequence $\{F^{(k)}\}$ converging?

(iii) are the necessary and sufficient conditions for the solution satisfied?

The decision as to whether a sequence is converging is necessarily speculative. The criterion used in the present routines is to assume convergence if the relative change occurring between two successive iterations is less than some prescribed quantity. Criterion (iii) is the most reliable but often the conditions cannot be checked fully because not all the required information may be available.

2.6.2. Checking results

Little a priori guidance can be given as to the quality of the solution found by a nonlinear optimization algorithm, since no guarantees can be given that the methods will always work. Therefore, it is necessary for the user to check the computed solution even if the routine reports success. Frequently a ' solution' may have been found even when the routine does not report a success. The reason for this apparent contradiction is that the routine needs to assess the accuracy of the solution. This assessment is not an exact process and consequently may be unduly pessimistic. Any 'solution' is in general only an approximation to the exact solution, and it is possible that the accuracy specified by the user is too stringent.

Further confirmation can be sought by trying to check whether or not convergence tests are almost satisfied, or whether or not some of the sufficient conditions are nearly satisfied. When it is thought that a routine has returned a non-zero value of IFAIL only because the requirements for 'success' were too stringent it may be worth restarting with increased convergence tolerances.

For nonlinearly-constrained problems, check whether the solution returned is feasible, or nearly feasible; if not, the solution returned is not an adequate solution.

Confidence in a solution may be increased by resolving the problem with a different initial approximation to the solution. See Section 8.3 of Gill et al [5] for further information.

2.6.3. Monitoring progress

Many of the routines in the Chapter have facilities to allow the user to monitor the progress of the minimization process, and users are encouraged to make use of these facilities. Monitoring information can be a great aid in assessing whether or not a satisfactory solution has been obtained, and in indicating difficulties in the minimization problem or in the routine's ability to cope with the problem.

The behaviour of the function, the estimated solution and first derivatives can help in deciding whether a solution is acceptable and what to do in the event of a return with a non-zero value of IFAIL.

2.6.4. Confidence intervals for least-squares solutions

When estimates of the parameters in a nonlinear least-squares problem have been found, it may be necessary to estimate the variances of the parameters and the fitted function. These can be calculated from the Hessian of F(x) at the solution.

In many least-squares problems, the Hessian is adequately approximated at the solution by $G=2J^TJ$ (see Section 2.4.3). The Jacobian, J, or a factorization of J is returned by all the comprehensive least-squares routines and, in addition, a routine is supplied in the Library to estimate variances of the parameters following the use of most of the nonlinear least-squares routines, in the case that $G=2J^TJ$ is an adequate approximation.

Let H be the inverse of G, and S be the sum of squares, both

calculated at the solution x; an unbiased estimate of the variance of the ith parameter x_i is

$$\mathrm{var}\, x_i = \frac{2S}{m-n} H_{ii}$$

and an unbiased estimate of the covariance of x_i and x_j is

$$\mathrm{covar}(x_i,x_j)= \frac{2S}{m-n} H_{ij} .$$

If x^* is the true solution, then the 100(1-(beta)) confidence

interval on x is

$$x_i - \sqrt{\mathrm{var}\, x_i}.t_{(1-(beta)/2,m-n)} < x_i^* < x_i$$

$$+ \sqrt{\mathrm{var}\, x_i}.t_{(1-(beta)/2,m-n)} , \quad i=1,2,...,n$$

where $t_{(1-(beta)/2,m-n)}$ is the 100(1-(beta))/2 percentage point of the t-distribution with m-n degrees of freedom.

In the majority of problems, the residuals f_i, for i=1,2,...,m, contain the difference between the values of a model function (phi)(z,x) calculated for m different values of the independent variable z, and the corresponding observed values at these points. The minimization process determines the parameters, or

constants x, of the fitted function (phi)(z,x). For any value, z, of the independent variable z, an unbiased estimate of the variance of (phi) is

n n

```
                   2S  --   -- [ dd(phi)] [ dd(phi)]
        var (phi)= --- >    >  [ -------] [ -------] H  .
                   m-n --   -- [  ddx   ] [  ddx   ]  ij
                       i=1 j=1[     i  ]z[     j  ]z
```

The 100(1-(beta)) confidence interval on F at the point z is

```
                                                 *
(phi)(z,x)-\/var (phi).t               < (phi)(z,x )
                        ((beta)/2,m-n)

                   < (phi)(z,x) +\/var (phi).t              .
                                              ((beta)/2,m-n)
```

For further details on the analysis of least-squares solutions see Bard [1] and Wolberg [7].

3. Recommendations on Choice and Use of Routines

The choice of routine depends on several factors: the type of problem (unconstrained, etc.); the level of derivative information available (function values only, etc.); the experience of the user (there are easy-to-use versions of some routines); whether or not storage is a problem; and whether computational time has a high priority.

3.1. Choice of Routine

Routines are provided to solve the following types of problem:

Nonlinear Programming	E04UCF
Quadratic Programming	E04NAF
Linear Programming	E04MBF
Nonlinear Function (using 1st derivatives)	E04DGF
Nonlinear Function, unconstrained or simple bounds (using function values only)	E04JAF
Nonlinear least-squares (using function values only)	E04FDF
Nonlinear least-squares (using function values and 1st derivatives)	E04GCF

E04UCF can be used to solve unconstrained, bound-constrained and linearly-constrained problems.

E04NAF can be used as a comprehensive linear programming solver; however, in most cases the easy-to-use routine E04MBFwill be adequate.

E04MBF can be used to obtain a feasible point for a set of linear constraints.

E04DGF can be used to solve large scale unconstrained problems.

The routines can be used to solve problems in a single variable.

3.2. Service Routines

One of the most common errors in use of optimization routines is that the user's subroutines incorrectly evaluate the relevant partial derivatives. Because exact gradient information normally enhances efficiency in all areas of optimization, the user should be encouraged to provide analytical derivatives whenever possible. However, mistakes in the computation of derivatives can result in serious and obscure run-time errors, as well as complaints that the Library routines are incorrect.

E04UCF incorporates a check on the gradients being supplied and users are encouraged to utilize this option; E04GCF also incorporates a call to a derivative checker.

E04YCF estimates selected elements of the variance-covariance matrix for the computed regression parameters following the use of a nonlinear least-squares routine.

3.3. Function Evaluations at Infeasible Points

Users must not assume that the routines for constrained problems will require the objective function to be evaluated only at points which satisfy the constraints, i.e., feasible points. In the first place some of the easy-to-use routines call a service routine which will evaluate the objective function at the user-supplied initial point, and at neighbouring points (to check user-supplied derivatives or to estimate intervals for finite differencing). Apart from this, all routines will ensure that any evaluations of the objective function occur at points which approximately satisfy any simple bounds or linear constraints. Satisfaction of such constraints is only approximate because:

(a) routines which have a parameter FEATOL may allow such constraints to be violated by a margin specified by FEATOL;

(b) routines which estimate derivatives by finite differences may require function evaluations at points which just violate such constraints even though the current iteration just satisfies them.

There is no attempt to ensure that the current iteration satisfies any nonlinear constraints. Users who wish to prevent their objective function being evaluated outside some known region (where it may be undefined or not practically computable), may try to confine the iteration within this region by imposing suitable simple bounds or linear constraints (but beware as this may create new local minima where these constraints are active).

Note also that some routines allow the user-supplied routine to return a parameter (MODE) with a negative value to force an immediate clean exit from the minimization when the objective function cannot be evaluated.

3.4. Related Problems

Apart from the standard types of optimization problem, there are other related problems which can be solved by routines in this or other chapters of the Library.

E04MBF can be used to find a feasible point for a set of linear constraints and simple bounds.

Two routines in Chapter F04 solve linear least-squares problems,

```
                m                        n
                --      2                --
i.e., minimize  >  r (x)  where r (x)=b - >  a  x .
```

```
           --  i            i     i  --  ij j
           i=1                       j=1
```

E02GAF solves an overdetermined system of linear equations in the

```
                          m
                          --
l  norm, i.e., minimizes  >  |r (x)|, with r  as above.
 1                        --   i            i
                          i=1
```

        E04 -- Minimizing or Maximizing a Function                E04DGF
                E04DGF -- NAG Foundation Library Routine Document

        Note: Before using this routine, please read the Users' Note for
        your implementation to check implementation-dependent details.
        The symbol (*) after a NAG routine name denotes a routine that is
        not included in the Foundation Library.

        Note for users via the Axiom system: the interface to this routine
        has been enhanced for use with Axiom and is slightly different to
        that offered in the standard version of the Foundation Library.  In
        particular, the optional parameters of the NAG routine are now
        included in the parameter list.  These are described in section
        5.1.2, below.

        1. Purpose

        E04DGF minimizes an unconstrained nonlinear function of several
        variables using a pre-conditioned, limited memory quasi-Newton
        conjugate gradient method. First derivatives are required. The
        routine is intended for use on large scale problems.

        2. Specification

               SUBROUTINE E04DGF(N,OBJFUN,ITER,OBJF,OBJGRD,X,IWORK,WORK,IUSER,
              1                  USER,ES,FU,IT,LIN,LIST,MA,OP,PR,STA,STO,
              2                  VE,IFAIL)
               INTEGER           N, ITER, IWORK(N+1), IUSER(*),
              1                  IT, PR, STA, STO, VE, IFAIL
               DOUBLE PRECISION OBJF, OBJGRD(N), X(N), WORK(13*N), USER(*)
              1                  ES, FU, LIN, OP, MA
               LOGICAL           LIST
               EXTERNAL          OBJFUN
```

3. Description

E04DGF uses a pre-conditioned conjugate gradient method and is based upon algorithm PLMA as described in Gill and Murray [1] and Gill et al [2] Section 4.8.3.

The algorithm proceeds as follows:

Let x_0 be a given starting point and let k denote the current iteration, starting with k=0. The iteration requires g_k, the gradient vector evaluated at x_k, the kth estimate of the minimum. At each iteration a vector p_k (known as the direction of search) is computed and the new estimate x_{k+1} is given by $x_k+(\alpha)_k p_k$ where $(\alpha)_k$ (the step length) minimizes the function $F(x_k+(\alpha)_k p_k)$ with respect to the scalar $(\alpha)_k$. A choice of initial step $(\alpha)_0$ is taken as

$$(\alpha)_0=\min\{1,2|F_k-F_{est}|/g_k^T g_k\}$$

where F_{est} is a user-supplied estimate of the function value at the solution. If F_{est} is not specified, the software always chooses the unit step length for $(\alpha)_0$. Subsequent step length estimates are computed using cubic interpolation with safeguards.

A quasi-Newton method can be used to compute the search direction p_k by updating the inverse of the approximate Hessian (H_k) and computing

$$p_{k+1} = -H_{k+1} g_{k+1} \qquad (1)$$

The updating formula for the approximate inverse is given by

$$H_{k+1} = H_k - \frac{1}{y_k^T s_k}\left(H_k y_k s_k^T + s_k y_k^T H_k\right) + \frac{1}{y_k^T s_k}\left(1 + \frac{y_k^T H_k y_k}{y_k^T s_k}\right) s_k s_k^T \qquad (2)$$

where $y_k = g_{k-1} - g_k$ and $s_k = x_{k+1} - x_k = (alpha)_k p_k$.

The method used by E04DGF to obtain the search direction is based upon computing p_{k+1} as $-H_{k+1} g_{k+1}$ where H_{k+1} is a matrix obtained by updating the identity matrix with a limited number of quasi-Newton corrections. The storage of an n by n matrix is avoided by storing only the vectors that define the rank two corrections - hence the term limited-memory quasi-Newton method. The precise method depends upon the number of updating vectors stored. For example, the direction obtained with the 'one-step' limited memory update is given by (1) using (2) with H_k equal to the identity matrix, viz.

$$p_{k+1} = -g_{k+1} + \frac{1}{y_k^T s_k}\left(s_k^T g_{k+1} y_k + y_k^T g_{k+1} s_k\right) - \frac{s_k^T g_{k+1}}{y_k^T s_k}\left(1 + \frac{y_k^T y_k}{y_k^T s_k}\right) s_k$$

E04DGF uses a two-step method described in detail in Gill and Murray [1] in which restarts and pre-conditioning are incorporated. Using a limited-memory quasi-Newton formula, such as the one above, guarantees p_{k+1} to be a descent direction if all the inner products y_k^T are positive for all vectors y_k and s_k used in the updating formula.

The termination criterion of E04DGF is as follows:

Let (tau) specify a parameter that indicates the number of

F

correct figures desired in F_k (τ_F is equivalent to Optimality Tolerance in the optional parameter list, see Section 5.1). If the following three conditions are satisfied

(i) $F_{k-1} - F_k < \tau_F (1+|F_k|)$

(ii) $||x_{k-1} - x_k|| < \sqrt{\tau_F}\,(1+||x_k||)$

(iii) $||g_k|| <= \sqrt[3]{\tau_F}\,(1+|F_k|)$ or $||g_k|| < \epsilon_A$,
where ϵ_A is the absolute error associated with computing the objective function

then the algorithm is considered to have converged. For a full discussion on termination criteria see Gill et al [2] Chapter 8.

5. Parameters

1: N -- INTEGER Input
On entry: the number n of variables. Constraint: N >= 1.

2: OBJFUN -- SUBROUTINE, supplied by the user. External Procedure
OBJFUN must calculate the objective function F(x) and its gradient for a specified n element vector x.

Its specification is:

```
      SUBROUTINE OBJFUN (MODE, N, X, OBJF, OBJGRD,
     1                   NSTATE, IUSER, USER)
      INTEGER          MODE, N, NSTATE, IUSER(*)
      DOUBLE PRECISION X(N), OBJF, OBJGRD(N), USER(*)
```

1: MODE -- INTEGER Input/Output

```
         MODE is a flag that the user may set within OBJFUN to
         indicate a failure in the evaluation of the objective
         function. On entry: MODE is always non-negative. On
         exit: if MODE is negative the execution of E04DGF is
         terminated with IFAIL set to MODE.

     2:  N -- INTEGER                                    Input
         On entry: the number n of variables.

     3:  X(N) -- DOUBLE PRECISION array                  Input
         On entry: the point x at which the objective function
         is required.

     4:  OBJF -- DOUBLE PRECISION                       Output
         On exit: the value of the objective function F at the
         current point x.

     5:  OBJGRD(N) -- DOUBLE PRECISION array            Output
                                                 ddF
         On exit: OBJGRD(i) must contain the value of  ---- at
                                                 ddx
                                                    i
         the point x, for i=1,2,...,n.

     6:  NSTATE -- INTEGER                               Input
         On entry: NSTATE will be 1 on the first call of OBJFUN
         by E04DGF, and is 0 for all subsequent calls. Thus, if
         the user wishes, NSTATE may be tested within OBJFUN in
         order to perform certain calculations once only. For
         example the user may read data or initialise COMMON
         blocks when NSTATE = 1.

     7:  IUSER(*) -- INTEGER array              User Workspace

     8:  USER(*) -- DOUBLE PRECISION array      User Workspace
         OBJFUN is called from E04DGF with the parameters IUSER
         and USER as supplied to E04DGF. The user is free to use
         arrays IUSER and USER to supply information to OBJFUN
         as an alternative to using COMMON.
    OBJFUN must be declared as EXTERNAL in the (sub)program
    from which E04DGF is called. Parameters denoted as
    Input must not be changed by this procedure.

 3:  ITER -- INTEGER                                    Output
    On exit: the number of iterations performed.

 4:  OBJF -- DOUBLE PRECISION                           Output
    On exit: the value of the objective function F(x) at the
    final iterate.
 5:  OBJGRD(N) -- DOUBLE PRECISION array                  Output
     On exit: the objective gradient at the final iterate.

 6:  X(N) -- DOUBLE PRECISION array                 Input/Output
     On entry: an initial estimate of the solution. On exit: the
     final estimate of the solution.

 7:  IWORK(N+1) -- INTEGER array                       Workspace

 8:  WORK(13*N) -- DOUBLE PRECISION array              Workspace

 9:  IUSER(*) -- INTEGER array                    User Workspace
     Note: the dimension of the array IUSER must be at least 1.
     This array is not used by E04DGF, but is passed directly to
     routine OBJFUN and may be used to supply information to
     OBJFUN.

10:  USER(*) -- DOUBLE PRECISION array            User Workspace
     Note: the dimension of the array USER must be at least 1.
     This array is not used by E04DGF, but is passed directly to
     routine OBJFUN and may be used to supply information to
     OBJFUN.

11:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. Users who are
     unfamiliar with this parameter should refer to the Essential
     Introduction for details.

     On exit: IFAIL = 0 unless the routine detects an error or
     gives a warning (see Section 6).

     For this routine, because the values of output parameters
     may be useful even if IFAIL /=0 on exit, users are
     recommended to set IFAIL to -1 before entry. It is then
     essential to test the value of IFAIL on exit.

5.1. Optional Input Parameters

Several optional parameters in E04DGF define choices in the
behaviour of the routine. In order to reduce the number of formal
parameters of E04DGF these optional parameters have associated
default values (see Section 5.1.3) that are appropriate for most
problems. Therefore the user need only specify those optional
parameters whose values are to be different from their default
values.

The remainder of this section can be skipped by users who wish to
use the default values for all optional parameters. A complete
list of optional parameters and their default values is given in
```

Section 5.1.3.

5.1.1. Specification of the Optional Parameters

Optional parameters may be specified by calling one, or both, of E04DJF and E04DKF prior to a call to E04DGF.

E04DJF reads options from an external options file, with Begin and End as the first and last lines respectively and each intermediate line defining a single optional parameter. For example,

```
      Begin
        Print Level = 1
      End
```

The call

```
      CALL E04DJF(IOPTNS, INFORM)
```

can then be used to read the file on unit IOPTNS. INFORM will be zero on successful exit. E04DJF should be consulted for a full description of this method of supplying optional parameters.

E04DKF can be called to supply options directly, one call being necessary for each optional parameter.

For example,

```
      CALL E04DKF('Print level = 1')
```

E04DKF should be consulted for a full description of this method of supplying optional parameters.

All optional parameters not specified by the user are set to their default values. Optional parameters specified by the user are unaltered by E04DGF (unless they define invalid values) and so remain in effect for subsequent calls to E04DGF, unless altered by the user.

5.1.2. Description of the Optional Parameters

The following list (in alphabetical order) gives the valid options. For each option, we give the keyword, any essential optional qualifiers, the default value, and the definition. The minimum valid abbreviation of each keyword is underlined. If no characters of an optional qualifier are underlined, the qualifier may be omitted. The letter a denotes a phrase (character string) that qualifies an option. The letters i and r denote INTEGER and real values required with certain options. The number (epsilon) is a generic notation for machine precision, and (epsilon)$_R$ denotes the relative precision of the objective function (the optional parameter Function Precision; see below).

Defaults

This special keyword may be used to reset the default values following a call to E04DGF.

Estimated Optimal Function Value r

   (Axiom parameter ES)

This value of r specifies the user-supplied guess of the optimum objective function value. This value is used by E04DGF to calculate an initial step length (see Section 3). If the value of r is not specified by the user (the default), then this has the effect of setting the initial step length to unity. It should be noted that for badly scaled functions a unit step along the steepest descent direction will often compute the function at very large values of x.

Function Precision r Default = (epsilon)$^{0.9}$

   (Axiom parameter FU)

The parameter defines (epsilon)$_R$, which is intended to be a measure of the accuracy with which the problem function F can be computed. The value of (epsilon)$_R$ should reflect the relative precision of 1+|F(x)|; i.e. (epsilon)$_R$ acts as a relative precision when |F| is large, and as an absolute precision when |F| is small. For example, if F(x) is typically of order 1000 and the first six significant digits are known to be correct, an appropriate value for (epsilon)$_R$ would be 1.0E-6. In contrast, if F(x) is typically of order 10^{-4} and the first six significant digits are known to be correct, an appropriate value for (epsilon)$_R$ would be 1.0E-10. The choice of (epsilon)$_R$ can be quite complicated for badly scaled problems; see Chapter 8 of Gill and Murray [2], for a discussion of scaling techniques. The default value is appropriate for most simple functions that are

```
computed with full accuracy. However when the accuracy of the
computed function values is known to be significantly worse than
full precision, the value of (epsilon)  should be large enough so
                                      R
that E04DGF will not attempt to distinguish between function
values that differ by less than the error inherent in the
calculation. If 0<=r<(epsilon), where (epsilon) is the machine
precision then the default value is used.

Iteration Limit  i Default = max(50,5n)

Iters

Itns

   (Axiom parameter IT)

The value i (i>=0) specifies the maximum number of iterations
allowed before termination. If i<0 the default value is used. See
Section 8 for further information.

Linesearch Tolerance  r Default = 0.9

   (Axiom parameter LIN)

The value r (0<=r<1) controls the accuracy with which the step
(alpha) taken during each iteration approximates a minimum of the
function along the search direction (the smaller the value of r,
the more accurate the linesearch). The default value r=0.9
requests an inaccurate search, and is appropriate for most
problems. A more accurate search may be appropriate when it is
desirable to reduce the number of iterations - for example, if
the objective function is cheap to evaluate.

List     Default =  List
Nolist

   (Axiom parameter LIST)

Normally each optional parameter specification is printed as it
is supplied. Nolist may be used to suppress the printing and List
may be used to restore printing.
                                  10
Maximum Step Length  r Default = 10

   (Axiom parameter MA)

The value r (r>0) defines the maximum allowable step length for
the line search. If r<=0 the default value is used.
```

Optimality Tolerance r Default = $(epsilon)^{0.8}$

(Axiom parameter OP)

The parameter r ($(epsilon)_R$ <=r<1) specifies the accuracy to which the user wishes the final iterate to approximate a solution of the problem. Broadly speaking, r indicates the number of correct figures desired in the objective function at the solution. For example, if r is 10^{-6} and E04DGF terminates successfully, the final value of F should have approximately six correct figures. E04DGF will terminate successfully if the iterative sequence of x -values is judged to have converged and the final point satisfies the termination criteria (see Section 3, where $(tau)_F$ represents Optimality Tolerance).

Print Level i Default = 10

(Axiom parameter PR)

The value i controls the amount of printout produced by E04DGF. The following levels of printing are available.

i	Output.
0	No output.
1	The final solution.
5	One line of output for each iteration.
10	The final solution and one line of output for each iteration.

Start Objective Check at Variable i Default = 1

(Axiom parameter STA)

Stop Objective Check at Variable i Default = n

(Axiom parameter STO)

These keywords take effect only if Verify Level > 0 (see below). They may be used to control the verification of gradient elements computed by subroutine OBJFUN. For example if the first 30 variables appear linearly in the objective, so that the

corresponding gradient elements are constant, then it is
reasonable to specify Start Objective Check at Variable 31.

Verify Level i Default = 0

Verify	No
Verify Level	-1
Verify Level	0
Verify	
Verify	Yes
Verify Objective Gradients	
Verify Gradients	
Verify Level	1

(Axiom parameter VE)

These keywords refer to finite-difference checks on the gradient
elements computed by the user-provided subroutine OBJFUN. It is
possible to set Verify Level in several ways, as indicated above.
For example, the gradients will be verified if Verify, Verify
Yes, Verify Gradients, Verify Objective Gradients or Verify Level
= 1 is specified.

If i<0 then no checking will be performed. If i>0 then the
gradients will be verified at the user-supplied point. If i=0
only a 'cheap' test will be performed, requiring one call to
OBJFUN. If i=1, a more reliable (but more expensive) check will
be made on individual gradient components, within the ranges
specified by the Start and Stop keywords as described above. A
result of the form OK or BAD? is printed by E04DGF to indicate
whether or not each component appears to be correct.

5.1.3. Optional parameter checklist and default values

For easy reference, the following sample list shows all valid
keywords and their default values. The default options Function
Precision and Optimality Tolerance depend upon (epsilon), the
machine precision.

Optional Parameters	Default Values
Estimated Optimal Function Value	

Function precision	$(\text{epsilon})^{0.9}$
Iterations	max(50,5n)
Linesearch Tolerance	0.9
Maximum Step Length	10^{10}
List/Nolist	List
Optimality Tolerance	$(\text{epsilon})^{0.8}$
Print Level	10
Start Objective Check at Variable	1
Stop Objective Check at Variable	n
Verify Level	0

5.2. Description of Printed Output

The level of printed output from E04DGF is controlled by the user (see the description of Print Level in Section 5.1).

When Print Level >= 5, the following line of output is produced at each iteration.

Itn	is the iteration count.
Step	is the step (alpha) taken along the computed search direction. On reasonably well-behaved problems, the unit step will be taken as the solution is approached.
Nfun	is the cumulated number of evaluations of the objective function needed for the linesearch. Evaluations needed for the estimation of the gradients by finite differences are not included. Nfun is printed as a guide to the amount of work required for the linesearch. E04DGF will perform at most 16 function evaluations per iteration.
Objective	is the value of the objective function.

```
Norm G          is the Euclidean norm of the gradient of the
                objective function.

Norm X          is the Euclidean norm of x.

Norm (X(k-1)-X(k)) is the Euclidean norm of x   -x .
                                              k-1  k

When Print Level = 1 or Print Level >= 10 then the solution at
the end of execution of E04DGF is printed out.

The following describes the printout for each variable:

Variable        gives the name (VARBL) and index j (j = 1 to n) of
                the variable

Value           is the value of the variable at the final iterate

Gradient Value is the value of the gradient of the objective
                function with respect to the jth variable at the
                final iterate

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

On exit from E04DGF, IFAIL should be tested. If Print Level > 0
then a short description of IFAIL is printed.

Errors and diagnostics indicated by IFAIL from E04DGF are as
follows:

IFAIL< 0
     A negative value of IFAIL indicates an exit from E04DGF
     because the user set MODE negative in routine OBJFUN. The
     value of IFAIL will be the same as the user's setting of
     MODE.

IFAIL= 1
     Not used by this routine.

IFAIL= 2
     Not used by this routine.

IFAIL= 3
     The maximum number of iterations has been performed. If the
     algorithm appears to be making progress the iterations value
     may be too small (see Section 5.1.2) so the user should
     increase iterations and rerun E04DGF. If the algorithm seems
     to be 'bogged down',the user should check for incorrect
     gradients or ill-conditioning as described below under IFAIL
     = 6.

IFAIL= 4
     The computed upper bound on the step length taken during the
     linesearch was too small. A rerun with an increased value of
     the Maximum Step Length ((rho) say) may be successful unless
              10
     (rho)>=10   (the default value), in which case the current
     point cannot be improved upon.

IFAIL= 5
     Not used by this routine.

IFAIL= 6
     A sufficient decrease in the function value could not be
     attained during the final linesearch. If the subroutine
     OBJFUN computes the function and gradients correctly, then
     this may occur because an overly stringent accuracy has been
     requested, i.e., Optimality Tolerance is too small or if the
     minimum lies close to a step length of zero. In this case
     the user should apply the four tests described in Section 3
     to determine whether or not the final solution is acceptable
     (the user will need to set Print Level >= 5). For a
     discussion of attainable accuracy see Gill and Murray [2].

     If many iterations have occurred in which essentially no
     progress has been made or E04DGF has failed to move from the
     initial point, subroutine OBJFUN may be incorrect. The user
     should refer to the comments below under IFAIL = 7 and check
     the gradients using the Verify parameter. Unfortunately,
     there may be small errors in the objective gradients that
     cannot be detected by the verification process. Finite-
     difference approximations to first derivatives are
     catastrophically affected by even small inaccuracies.

IFAIL= 7
     Large errors were found in the derivatives of the objective
     function. This value of IFAIL will occur if the verification
     process indicated that at least one gradient component had
     no correct figures. The user should refer to the printed
     output to determine which elements are suspected to be in
     error.

     As a first step, the user should check that the code for the
     objective values is correct - for example, by computing the
```

function at a point where the correct value is known. However, care should be taken that the chosen point fully tests the evaluation of the function. It is remarkable how often the values x=0 or x=1 are used to test function evaluation procedures, and how often the special properties of these numbers make the test meaningless.

Special care should be used in this test if computation of the objective function involves subsidiary data communicated in COMMON storage. Although the first evaluation of the function may be correct, subsequent calculations may be in error because some of the subsidiary data has accidentally been overwritten.

Errors in programming the function may be quite subtle in that the function value is 'almost' correct. For example, the function may not be accurate to full precision because of the inaccurate calculation of a subsidiary quantity, or the limited accuracy of data upon which the function depends. A common error on machines where numerical calculations are usually performed in double precision is to include even one single-precision constant in the calculation of the function; since some compilers do not convert such constants to double precision, half the correct figures may be lost by such a seemingly trivial error.

IFAIL= 8

The gradient (g) at the starting point is too small. The value $g^T g$ is less than $(epsilon)_m |F(x_o)|$, where $(epsilon)_m$ is the machine precision.

The problem should be rerun at a different starting point.

IFAIL= 9

On entry N < 1.

7. Accuracy

On successful exit the accuracy of the solution will be as defined by the optional parameter Optimality Tolerance.

8. Further Comments

Problems whose Hessian matrices at the solution contain sets of clustered eigenvalues are likely to be minimized in significantly fewer than n iterations. Problems without this property may require anything between n and 5n iterations, with approximately 2n iterations being a common figure for moderately difficult

```
        problems.

        9. Example

        To find a minimum of the function

                              x
                               1   2   2
                           F=e  (4x +2x +4x x +2x +1).
                                    1   2   1 2   2

        The example program is not reproduced here. The source code for
        all example programs is distributed with the NAG Foundation
        Library software and should be available on-line.

     E04DJF(3NAG)      Foundation Library (12/10/92)      E04DJF(3NAG)

          E04 -- Minimizing or Maximizing a Function                E04DJF
                  E04DJF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          To supply optional parameters to E04DGF from an external file.

          2. Specification
```

```
       SUBROUTINE E04DJF (IOPTNS, INFORM)
       INTEGER          IOPTNS, INFORM
```

3. Description

E04DJF may be used to supply values for optional parameters to E04DGF. E04DJF reads an external file and each line of the file defines a single optional parameter. It is only necessary to supply values for those parameters whose values are to be different from their default values.

Each optional parameter is defined by a single character string of up to 72 characters, consisting of one or more items. The items associated with a given option must be separated by spaces, or equal signs (=). Alphabetic characters may be upper or lower case. The string

```
      Print level = 1
```

is an example of a string used to set an optional parameter. For each option the string contains one or more of the following items:

(a)   A mandatory keyword.

(b)   A phrase that qualifies the keyword.

(c)   A number that specifies an INTEGER or real value. Such numbers may be up to 16 contiguous characters in Fortran 77's I, F, E or D formats, terminated by a space if this is not the last item on the line.

Blank strings and comments are ignored. A comment begins with an asterisk (*) and all subsequent characters in the string are regarded as part of the comment.

The file containing the options must start with begin and must finish with end An example of a valid options file is:

```
      Begin * Example options file
        Print level = 10
      End
```

Normally each line of the file is printed as it is read, on the current advisory message unit (see X04ABF), but printing may be suppressed using the keyword nolist. To suppress printing of begin, nolist must be the first option supplied as in the file:

```
      Begin
        Nolist
        Print level = 10
      End
```

Printing will automatically be turned on again after a call to E04DGF and may be turned on again at any time by the user by using the keyword list.

Optional parameter settings are preserved following a call to E04DGF, and so the keyword defaults is provided to allow the user to reset all the optional parameters to their default values prior to a subsequent call to E04DGF.

A complete list of optional parameters, their abbreviations, synonyms and default values is given in Section 5.1 of the routine document for E04DGF.

4. References

None.

5. Parameters

```
 1:  IOPTNS -- INTEGER                                      Input
     On entry: IOPTNS must be the unit number of the options
     file. Constraint: 0 <= IOPTNS <= 99.

 2:  INFORM -- INTEGER                                     Output
     On exit: INFORM will be zero if an options file with the
     correct structure has been read. Otherwise INFORM will be
     positive. Positive values of INFORM indicate that an options
     file may not have been successfully read as follows:
     INFORM = 1
           IOPTNS is not in the range [0,99].

     INFORM = 2
           begin was found, but end-of-file was found before end
           was found.

     INFORM = 3
           end-of-file was found before begin was found.
```

6. Error Indicators and Warnings

If a line is not recognised as a valid option, then a warning message is output on the current advisory message unit (see X04ABF).

7. Accuracy

```
         Not applicable.

         8. Further Comments

         E04DKF may also be used to supply optional parameters to E04DGF.

         9. Example

         See the example for E04DGF.

\end{verbatim}
\endscroll
\end{page}

         your implementation to check implementation-dependent details.
         The symbol (*) after a NAG routine name denotes a routine that is
         not included in the Foundation Library.

         1. Purpose

         To supply individual optional parameters to E04DGF.

         2. Specification

                SUBROUTINE E04DKF (STRING)
                CHARACTER*(*)    STRING
```

3. Description

E04DKF may be used to supply values for optional parameters to E04DGF. It is only necessary to call E04DKF for those parameters whose values are to be different from their default values. One call to E04DKF sets one parameter value.

Each optional parameter is defined by a single character string of up to 72 characters, consisting of one or more items. The items associated with a given option must be separated by spaces, or equal signs (=). Alphabetic characters may be upper or lower case. The string

```
      Print Level = 1
```

is an example of a string used to set an optional parameter. For each option the string contains one or more of the following items:

(a)   A mandatory keyword.

(b)   A phrase that qualifies the keyword.

(c)   A number that specifies an INTEGER or real value. Such numbers may be up to 16 contiguous characters in Fortran 77's I, F, E or D formats, terminated by a space if this is not the last item on the line.

Blank strings and comments are ignored. A comment begins with an asterisk (*) and all subsequent characters in the string are regarded as part of the comment.

Normally, each user-specified option is printed as it is defined, on the current advisory message unit (see X04ABF), but this printing may be suppressed using the keyword nolist Thus the statement

```
     CALL E04DKF ('Nolist')
```

suppresses printing of this and subsequent options. Printing will automatically be turned on again after a call to E04DGF, and may be turned on again at any time by the user, by using the keyword list.

Optional parameter settings are preserved following a call to E04DGF, and so the keyword defaults is provided to allow the user to reset all the optional parameters to their default values by the statement,

```
               CALL E04DKF ('Defaults')

          prior to a subsequent call to E04DGF.

          A complete list of optional parameters, their abbreviations,
          synonyms and default values is given in Section 5.1 of the
          routine document for E04DGF.

          4. References

          None.

          5. Parameters

           1:  STRING -- CHARACTER*(*)                                Input
               On entry: STRING must be a single valid option string. See
               Section 3 above, and Section 5.1 of the routine document for
               E04DGF.

          6. Error Indicators and Warnings

          If the parameter STRING is not recognised as a valid option
          string, then a warning message is output on the current advisory
          message unit (see X04ABF).

          7. Accuracy

          Not applicable.

          8. Further Comments

          E04DJF may also be used to supply optional parameters to E04DGF.

          9. Example

          See the example for E04DGF.

16.4.35 Finding an unconstrained minimum of a sum of squares

— nage.ht —

```
\begin{page}{manpageXXe04fdf}{NAG Documentation: e04fdf}
\beginscroll
\begin{verbatim}

     E04FDF(3NAG)      Foundation Library (12/10/92)      E04FDF(3NAG)

          E04 -- Minimizing or Maximizing a Function                E04FDF
                  E04FDF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          E04FDF is an easy-to-use algorithm for finding an unconstrained
          minimum of a sum of squares of m nonlinear functions in n
          variables (m>=n). No derivatives are required.

          It is intended for functions which are continuous and which have
          continuous first and second derivatives (although it will usually
          work even if the derivatives have occasional discontinuities).

          2. Specification

                 SUBROUTINE E04FDF (M, N, X, FSUMSQ, IW, LIW, W, LW, IFAIL)
                 INTEGER          M, N, IW(LIW), LIW, LW, IFAIL
                 DOUBLE PRECISION X(N), FSUMSQ, W(LW)

          3. Description

          This routine is essentially identical to the subroutine LSNDN1 in
          the National Physical Laboratory Algorithms Library. It is
          applicable to problems of the form

                                          m
                                          --        2
                             Minimize F(x)= >  [f (x)]
                                          --   i
                                          i=1

                              T
          where x=(x ,x ,...,x )  and m>=n. (The functions f (x) are often
                    1  2      n                            i
          referred to as 'residuals'.) The user must supply a subroutine
```

```
LSFUN1 to evaluate functions f (x) at any point x.
                              i

From a starting point supplied by the user, a sequence of points
is generated which is intended to converge to a local minimum of
the sum of squares. These points are generated using estimates of
the curvature of F(x).

4. References

      the Nonlinear Least-squares Problem. SIAM J. Numer. Anal. 15
      977--992.

5. Parameters

 1:  M -- INTEGER                                            Input

 2:  N -- INTEGER                                            Input
     On entry: the number m of residuals f (x), and the number n
                                          i
     of variables, x . Constraint: 1 <= N <= M.
                    j

 3:  X(N) -- DOUBLE PRECISION array                   Input/Output
     On entry: X(j) must be set to a guess at the jth component
     of the position of the minimum, for j=1,2,...,n. On exit:
     the lowest point found during the calculations. Thus, if
     IFAIL = 0 on exit, X(j) is the jth component of the position
     of the minimum.

 4:  FSUMSQ -- DOUBLE PRECISION                             Output
     On exit: the value of the sum of squares, F(x),
     corresponding to the final point stored in X.

 5:  IW(LIW) -- INTEGER array                            Workspace

 6:  LIW -- INTEGER                                          Input
     On entry: the length of IW as declared in the (sub)program
     from which E04FDF has been called. Constraint: LIW >= 1.

 7:  W(LW) -- DOUBLE PRECISION array                     Workspace

 8:  LW -- INTEGER                                           Input
     On entry: the length of W as declared in the (sub)program
     from which E04FDF is called. Constraints:
          LW >= N*(7 + N + 2*M + (N-1)/2) + 3*M, if N > 1,

          LW >= 9 + 5*>M, if N = 1.
 9:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. Users who are
     unfamiliar with this parameter should refer to the Essential
     Introduction for details.

     On exit: IFAIL = 0 unless the routine detects an error or
     gives a warning (see Section 6).

     For this routine, because the values of output parameters
     may be useful even if IFAIL /=0 on exit, users are
     recommended to set IFAIL to -1 before entry. It is then
     essential to test the value of IFAIL on exit.

5.1. Optional Parameters

     LSFUN1 -- SUBROUTINE, supplied by the user.
                                               External Procedure
     This routine must be supplied by the user to calculate the
     vector of values f (x) at any point x. Since the routine is
                       i
     not a parameter to E04FDF, it must be called LSFUN1. It
     should be tested separately before being used in conjunction
     with E04FDF (see the Chapter Introduction).

     Its specification is:

            SUBROUTINE LSFUN1 (M, N, XC, FVECC)
            INTEGER          M, N
            DOUBLE PRECISION XC(N), FVECC(M)

      1:  M -- INTEGER                                      Input

      2:  N -- INTEGER                                      Input
          On entry: the numbers m and n of residuals and
          variables, respectively.

      3:  XC(N) -- DOUBLE PRECISION array                   Input
          On entry: the point x at which the values of the f
                                                            i
          are required.

      4:  FVECC(M) -- DOUBLE PRECISION array               Output
          On exit: FVECC(i) must contain the value of f  at the
                                                      i
          point x, for i=1,2,...,m.
     LSFUN1 must be declared as EXTERNAL in the (sub)program
     from which E04FDF is called. Parameters denoted as
     Input must not be changed by this procedure.

6. Error Indicators and Warnings
```

```
Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry N < 1,

     or       M < N,

     or       LIW < 1,

     or       LW < N*(7 + N + 2*M + (N-1)/2) + 3*M, when N > 1,

     or       LW < 9 + 5*>M, when N = 1.

IFAIL= 2
     There have been 400*n calls of LSFUN1, yet the algorithm
     does not seem to have converged. This may be due to an
     awkward function or to a poor starting point, so it is worth
     restarting E04FDF from the final point held in X.

IFAIL= 3
     The final point does not satisfy the conditions for
     acceptance as a minimum, but no lower point could be found.

IFAIL= 4
     An auxiliary routine has been unable to complete a singular
     value decomposition in a reasonable number of sub-
     iterations.

IFAIL= 5

IFAIL= 6

IFAIL= 7

IFAIL= 8
     There is some doubt about whether the point x found by
     E04FDF is a minimum of F(x). The degree of confidence in the
     result decreases as IFAIL increases. Thus when IFAIL = 5, it
     is probable that the final x gives a good estimate of the
     position of a minimum, but when IFAIL = 8 it is very
     unlikely that the routine has found a minimum.

If the user is not satisfied with the result (e.g. because IFAIL
lies between 3 and 8), it is worth restarting the calculations
from a different starting point (not the point at which the
failure occurred) in order to avoid the region which caused the
```

failure. Repeated failure may indicate some defect in the formulation of the problem.

7. Accuracy

If the problem is reasonably well scaled and a successful exit is made, then, for a computer with a mantissa of t decimals, one would expect to get about t/2-1 decimals accuracy in the components of x and between t-1 (if F(x) is of order 1 at the minimum) and 2t-2 (if F(x) is close to zero at the minimum) decimals accuracy in F(x).

8. Further Comments

The number of iterations required depends on the number of variables, the number of residuals and their behaviour, and the distance of the starting point from the solution. The number of multiplications performed per iteration of E04FDF varies, but for m>>n is approximately $n*m^2 +O(n^3)$. In addition, each iteration makes at least n+1 calls of LSFUN1. So, unless the residuals can be evaluated very quickly, the run time will be dominated by the time spent in LSFUN1.

Ideally, the problem should be scaled so that the minimum value of the sum of squares is in the range (0,1), and so that at points a unit distance away from the solution the sum of squares is approximately a unit value greater than at the minimum. It is unlikely that the user will be able to follow these recommendations very closely, but it is worth trying (by guesswork), as sensible scaling will reduce the difficulty of the minimization problem, so that E04FDF will take less computer time.

When the sum of squares represents the goodness of fit of a nonlinear model to observed data, elements of the variance-covariance matrix of the estimated regression coefficients can be computed by a subsequent call to E04YCF, using information returned in segments of the workspace array W. See E04YCF for further details.

9. Example

To find least-squares estimates of x_1, x_2 and x_3 in the model

$$y=x_1 + \frac{t_1}{x\,t +x\,t}$$

```
                                      2 2  3 3

          using the 15 sets of data given in the following table.

                                y    t   t    t
                                      1   2    3
                               0.14  1.0 15.0 1.0
                               0.18  2.0 14.0 2.0
                               0.22  3.0 13.0 3.0
                               0.25  4.0 12.0 4.0
                               0.29  5.0 11.0 5.0
                               0.32  6.0 10.0 6.0
                               0.35  7.0  9.0 7.0
                               0.39  8.0  8.0 8.0
                               0.37  9.0  7.0 7.0
                               0.58 10.0  6.0 6.0
                               0.73 11.0  5.0 5.0
                               0.96 12.0  4.0 4.0
                               1.34 13.0  3.0 3.0
                               2.10 14.0  2.0 2.0
                               4.39 15.0  1.0 1.0

          The program uses (0.5, 1.0, 1.5) as the initial guess at the
          position of the minimum.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

16.4.36 Finding an unconstrained minimum of a sum of squares

— nage.ht —

```
\begin{page}{manpageXXe04gcf}{NAG Documentation: e04gcf}
\beginscroll
\begin{verbatim}

     E04GCF(3NAG)      Foundation Library (12/10/92)      E04GCF(3NAG)
```

E04 -- Minimizing or Maximizing a Function E04GCF

E04GCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E04GCF is an easy-to-use quasi-Newton algorithm for finding an unconstrained minimum of a sum of squares of m nonlinear functions in n variables (m>=n). First derivatives are required.

It is intended for functions which are continuous and which have continuous first and second derivatives (although it will usually work even if the derivatives have occasional discontinuities).

2. Specification

```
      SUBROUTINE E04GCF (M, N, X, FSUMSQ, IW, LIW, W, LW, IFAIL)
      INTEGER          M, N, IW(LIW), LIW, LW, IFAIL
      DOUBLE PRECISION X(N), FSUMSQ, W(LW)
```

3. Description

This routine is essentially identical to the subroutine LSFDQ2 in the National Physical Laboratory Algorithms Library. It is applicable to problems of the form

$$\text{Minimize } F(x)=\sum_{i=1}^{m}[f_i(x)]^2$$

where $x=(x_1,x_2,...,x_n)^T$ and m>=n. (The functions $f_i(x)$ are often referred to as 'residuals'.) The user must supply a subroutine LSFUN2 to evaluate the residuals and their first derivatives at any point x.

Before attempting to minimize the sum of squares, the algorithm checks LSFUN2 for consistency. Then, from a starting point supplied by the user, a sequence of points is generated which is intended to converge to a local minimum of the sum of squares. These points are generated using estimates of the curvature of

```
F(x).

4. References

[1]   Gill P E and Murray W (1978) Algorithms for the Solution of
      the Nonlinear Least-squares Problem. SIAM J. Numer. Anal. 15
      977--992.

5. Parameters

 1:  M -- INTEGER                                          Input

 2:  N -- INTEGER                                          Input
     On entry: the number m of residuals f (x), and the number n
                                          i
     of variables, x . Constraint: 1 <= N <= M.
                    j

 3:  X(N) -- DOUBLE PRECISION array                 Input/Output
     On entry: X(j) must be set to a guess at the jth component
     of the position of the minimum, for j=1,2,...,n. The routine
     checks the first derivatives calculated by LSFUN2 at the
     starting point, and so is more likely to detect an error in
     the user's routine if the initial X(j) are non-zero and
     mutually distinct. On exit: the lowest point found during
     the calculations. Thus, if IFAIL = 0 on exit, X(j) is the j
     th component of the position of the minimum.

 4:  FSUMSQ -- DOUBLE PRECISION                           Output
     On exit: the value of the sum of squares, F(x),
     corresponding to the final point stored in X.

 5:  IW(LIW) -- INTEGER array                          Workspace

 6:  LIW -- INTEGER                                        Input
     On entry: the length of IW as declared in the (sub)program
     from which E04GCF is called. Constraint: LIW >= 1.

 7:  W(LW) -- DOUBLE PRECISION array                   Workspace

 8:  LW -- INTEGER                                         Input
     On entry: the length of W as declared in the (sub)program
     from which E04GCF is called. Constraints:
          LW >= 2*N*(4 + N + M) + 3*M, if N > 1,

          LW >= 11 + 5*M, if N = 1.

 9:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. Users who are
     unfamiliar with this parameter should refer to the Essential
```

Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL /=0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

5.1. Optional Parameters

LSFUN2 -- SUBROUTINE, supplied by the user.

External Procedure

This routine must be supplied by the user to calculate the vector of values $f_i(x)$ and the Jacobian matrix of first derivatives $\frac{ddf_i}{ddx_j}$ at any point x. Since the routine is not a parameter to E04GCF, it must be called LSFUN2. It should be tested separately before being used in conjunction with E04GCF (see the Chapter Introduction).

Its specification is:

```
       SUBROUTINE LSFUN2 (M, N, XC, FVECC, FJACC, LJC)
       INTEGER          M, N, LJC
       DOUBLE PRECISION XC(N), FVECC(M), FJACC(LJC,N)
```

Important: The dimension declaration for FJACC must contain the variable LJC, not an integer constant.

1: M -- INTEGER Input

2: N -- INTEGER Input

On entry: the numbers m and n of residuals and variables, respectively.

3: XC(N) -- DOUBLE PRECISION array Input

On entry: the point x at which the values of the f_i and the $\frac{ddf_i}{ddx_j}$ are required.

4: FVECC(M) -- DOUBLE PRECISION array Output

```
          On exit: FVECC(i) must contain the value of f  at the
                                                      i
          point x, for i=1,2,...,m.

      5:  FJACC(LJC,N) -- DOUBLE PRECISION array           Output
                                                         ddf
                                                            i
          On exit: FJACC(i,j) must contain the value of  ---- at
                                                         ddx
                                                            j
          the point x, for i=1,2,...,m; j=1,2,...,n.

      6:  LJC -- INTEGER                                    Input
          On entry: the first dimension of the array FJACC.
     LSFUN2 must be declared as EXTERNAL in the (sub)program
     from which E04GCF is called. Parameters denoted as
     Input must not be changed by this procedure.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry N < 1,

     or       M < N,

     or       LIW < 1,

     or       LW < 2*N*(4 + N + M) + 3*M, when N > 1,

     or       LW < 9 + 5*>M, when N = 1.

IFAIL= 2
     There have been 50*n calls of LSFUN2, yet the algorithm does
     not seem to have converged. This may be due to an awkward
     function or to a poor starting point, so it is worth
     restarting E04GCF from the final point held in X.

IFAIL= 3
     The final point does not satisfy the conditions for
     acceptance as a minimum, but no lower point could be found.

IFAIL= 4
     An auxiliary routine has been unable to complete a singular
     value decomposition in a reasonable number of sub-
     iterations.
```

```
IFAIL= 5

IFAIL= 6

IFAIL= 7

IFAIL= 8
     There is some doubt about whether the point X found by
     E04GCF is a minimum of F(x). The degree of confidence in the
     result decreases as IFAIL increases. Thus, when IFAIL = 5,
     it is probable that the final x gives a good estimate of the
     position of a minimum, but when IFAIL = 8 it is very
     unlikely that the routine has found a minimum.

IFAIL= 9
     It is very likely that the user has made an error in forming
                      ddf
                         i
     the derivatives  ---- in LSFUN2.
                      ddx
                         j

If the user is not satisfied with the result (e.g. because IFAIL
lies between 3 and 8), it is worth restarting the calculations
from a different starting point (not the point at which the
failure occurred) in order to avoid the region which caused the
failure. Repeated failure may indicate some defect in the
formulation of the problem.

7. Accuracy

If the problem is reasonably well scaled and a successful exit is
made then, for a computer with a mantissa of t decimals, one
would expect to get t/2-1 decimals accuracy in the components of
x and between t-1 (if F(x) is of order 1 at the minimum) and 2t-2
(if F(x) is close to zero at the minimum) decimals accuracy in
F(x).

8. Further Comments

The number of iterations required depends on the number of
variables, the number of residuals and their behaviour, and the
distance of the starting point from the solution. The number of
multiplications performed per iteration of E04GCF varies, but for
                         2    3
m>>n is approximately n*m +O(n ). In addition, each iteration
makes at least one call of LSFUN2. So, unless the residuals and
their derivatives can be evaluated very quickly, the run time
will be dominated by the time spent in LSFUN2.
```

Ideally the problem should be scaled so that the minimum value of the sum of squares is in the range (0,1) and so that at points a unit distance away from the solution the sum of squares is approximately a unit value greater than at the minimum. It is unlikely that the user will be able to follow these recommendations very closely, but it is worth trying (by guesswork), as sensible scaling will reduce the difficulty of the minimization problem, so that E04GCF will take less computer time.

When the sum of squares represents the goodness of fit of a nonlinear model to observed data, elements of the variance-covariance matrix of the estimated regression coefficients can be computed by a subsequent call to E04YCF, using information returned in segments of the workspace array W. See E04YCF for further details.

9. Example

To find the least-squares estimates of x_1, x_2 and x_3 in the model

$$y=x_1 + \frac{t_1}{x_2 t_2 +x_3 t_3}$$

using the 15 sets of data given in the following table.

y	t_1	t_2	t_3
0.14	1.0	15.0	1.0
0.18	2.0	14.0	2.0
0.22	3.0	13.0	3.0
0.25	4.0	12.0	4.0
0.29	5.0	11.0	5.0
0.32	6.0	10.0	6.0
0.35	7.0	9.0	7.0
0.39	8.0	8.0	8.0
0.37	9.0	7.0	7.0
0.58	10.0	6.0	6.0
0.73	11.0	5.0	5.0
0.96	12.0	4.0	4.0
1.34	13.0	3.0	3.0
2.10	14.0	2.0	2.0
4.39	15.0	1.0	1.0

The program uses (0.5, 1.0, 1.5) as the initial guess at the

```
          position of the minimum.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

\end{verbatim}
\endscroll
\end{page}

16.4.37 Finding a minimum of a function

— nage.ht —

```
\begin{page}{manpageXXe04jaf}{NAG Documentation: e04jaf}
\beginscroll
\begin{verbatim}

     E04JAF(3NAG)      Foundation Library (12/10/92)      E04JAF(3NAG)

          E04 -- Minimizing or Maximizing a Function                 E04JAF
                  E04JAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          E04JAF is an easy-to-use quasi-Newton algorithm for finding a
          minimum of a function F(x ,x ,...,x ), subject to fixed upper and
                                   1  2      n
          lower bounds of the independent variables x ,x ,...,x , using
                                                     1  2      n
          function values only.

          It is intended for functions which are continuous and which have
          continuous first and second derivatives (although it will usually
          work even if the derivatives have occasional discontinuities).
```

2. Specification

```
       SUBROUTINE E04JAF (N, IBOUND, BL, BU, X, F, IW, LIW, W,
      1                   LW, IFAIL)
       INTEGER          N, IBOUND, IW(LIW), LIW, LW, IFAIL
       DOUBLE PRECISION BL(N), BU(N), X(N), F, W(LW)
```

3. Description

This routine is applicable to problems of the form:

$$\text{Minimize } F(x_1,x_2,\ldots,x_n) \text{ subject to } l_j \le x_j \le u_j, \; j=1,2,\ldots,n$$

when derivatives of F(x) are unavailable.

Special provision is made for problems which actually have no bounds on the x_j, problems which have only non-negativity bounds and problems in which $l_1=l_2=\ldots=l_n$ and $u_1=u_2=\ldots=u_n$. The user must supply a subroutine FUNCT1 to calculate the value of F(x) at any point x.

From a starting point supplied by the user there is generated, on the basis of estimates of the gradient and the curvature of F(x), a sequence of feasible points which is intended to converge to a local minimum of the constrained function. An attempt is made to verify that the final point is a minimum.

4. References

[1] Gill P E and Murray W (1976) Minimization subject to bounds on the variables. Report NAC 72. National Physical Laboratory.

5. Parameters

1: N -- INTEGER Input
On entry: the number n of independent variables.
Constraint: N >= 1.

2: IBOUND -- INTEGER Input
On entry: indicates whether the facility for dealing with bounds of special forms is to be used.

It must be set to one of the following values:
IBOUND = 0
if the user will be supplying all the l_j and u_j

individually.

IBOUND = 1
if there are no bounds on any x_j.

IBOUND = 2
if all the bounds are of the form $0<=x_j$.

IBOUND = 3
if $l_1=l_2=...=l_n$ and $u_1=u_2=...=u_n$.

3: BL(N) -- DOUBLE PRECISION array Input/Output
On entry: the lower bounds l_j.

If IBOUND is set to 0, the user must set BL(j) to l_j, for j=1,2,...,n. (If a lower bound is not specified for a particular x_j, the corresponding BL(j) should be set to -10^6.)

If IBOUND is set to 3, the user must set BL(1) to l_1; E04JAF will then set the remaining elements of BL equal to BL(1).
On exit: the lower bounds actually used by E04JAF.

4: BU(N) -- DOUBLE PRECISION array Input/Output
On entry: the upper bounds u_j.

If IBOUND is set to 0, the user must set BU(j) to u_j, for j=1,2,...,n. (If an upper bound is not specified for a particular x_j, the corresponding BU(j) should be set to 10^6.)

If IBOUND is set to 3, the user must set BU(1) to u_1; E04JAF will then set the remaining elements of BU equal to BU(1).
On exit: the upper bounds actually used by E04JAF.

5: X(N) -- DOUBLE PRECISION array Input/Output
On entry: X(j) must be set to an estimate of the jth component of the position of the minimum, for j=1,2,...,n.
On exit: the lowest point found during the calculations.

```
     Thus, if IFAIL = 0 on exit, X(j) is the jth component of the
     position of the minimum.

  6: F -- DOUBLE PRECISION                                  Output
     On exit: the value of F(x) corresponding to the final point
     stored in X.

  7: IW(LIW) -- INTEGER array                            Workspace

  8: LIW -- INTEGER                                          Input
     On entry: the length of IW as declared in the (sub)program
     from which E04JAF is called. Constraint: LIW >= N + 2.

  9: W(LW) -- DOUBLE PRECISION array                     Workspace

 10: LW -- INTEGER                                           Input
     On entry: the length of W as declared in the (sub)program
     from which E04JAF is called. Constraint: LW>=max(N*(N-
     1)/2+12*N,13).

 11: IFAIL -- INTEGER                                 Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. Users who are
     unfamiliar with this parameter should refer to the Essential
     Introduction for details.

     On exit: IFAIL = 0 unless the routine detects an error or
     gives a warning (see Section 6).

     For this routine, because the values of output parameters
     may be useful even if IFAIL /=0 on exit, users are
     recommended to set IFAIL to -1 before entry. It is then
     essential to test the value of IFAIL on exit. To suppress
     the output of an error message when soft failure occurs, set
     IFAIL to 1.

 5.1. Optional Parameters

     FUNCT1 -- SUBROUTINE, supplied by the user.
                                           External Procedure
     This routine must be supplied by the user to calculate the
     value of the function F(x) at any point x. Since this
     routine is not a parameter to E04JAF, it must be called
     FUNCT1. It should be tested separately before being used in
     conjunction with E04JAF (see the Chapter Introduction).

     Its specification is:

            SUBROUTINE FUNCT1 (N, XC, FC)
            INTEGER          N
            DOUBLE PRECISION XC(N), FC
      1:  N -- INTEGER                                      Input
          On entry: the number n of variables.

      2:  XC(N) -- DOUBLE PRECISION array                   Input
          On entry: the point x at which the function value is
          required.

      3:  FC -- DOUBLE PRECISION                           Output
          On exit: the value of the function F at the current
          point x.
     FUNCT1 must be declared as EXTERNAL in the (sub)program
     from which E04JAF is called. Parameters denoted as
     Input must not be changed by this procedure.
```

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

```
IFAIL= 1
     On entry N < 1,

     or       IBOUND < 0,

     or       IBOUND > 3,

     or       IBOUND = 0 and BL(j) > BU(j) for some j,

     or       IBOUND = 3 and BL(1) > BU(1),

     or       LIW < N + 2,

     or       LW<max(13,12*N+N*(N-1)/2).

IFAIL= 2
     There have been 400*n function evaluations, yet the
     algorithm does not seem to be converging. The calculations
     can be restarted from the final point held in X. The error
     may also indicate that F(x) has no minimum.

IFAIL= 3
     The conditions for a minimum have not all been met but a
     lower point could not be found and the algorithm has failed.

IFAIL= 4
     An overflow has occurred during the computation. This is an
     unlikely failure, but if it occurs the user should restart
     at the latest point given in X.

IFAIL= 5
```

IFAIL= 6

IFAIL= 7

IFAIL= 8

There is some doubt about whether the point x found by E04JAF is a minimum. The degree of confidence in the result decreases as IFAIL increases. Thus, when IFAIL = 5 it is probable that the final x gives a good estimate of the position of a minimum, but when IFAIL = 8 it is very unlikely that the routine has found a minimum.

IFAIL= 9

In the search for a minimum, the modulus of one of the variables has become very large ($\sim 10^6$). This indicates that there is a mistake in FUNCT1, that the user's problem has no finite solution, or that the problem needs rescaling (see Section 8).

If the user is dissatisfied with the result (e.g. because IFAIL = 5, 6, 7 or 8), it is worth restarting the calculations from a different starting point (not the point at which the failure occurred) in order to avoid the region which caused the failure. If persistent trouble occurs and the gradient can be calculated, it may be advisable to change to a routine which uses gradients (see the Chapter Introduction).

7. Accuracy

When a successful exit is made then, for a computer with a mantissa of t decimals, one would expect to get about t/2-1 decimals accuracy in x and about t-1 decimals accuracy in F, provided the problem is reasonably well scaled.

8. Further Comments

The number of iterations required depends on the number of variables, the behaviour of F(x) and the distance of the starting point from the solution. The number of operations performed in an iteration of E04JAF is roughly proportional to n^2. In addition, each iteration makes at least m+1 calls of FUNCT1, where m is the number of variables not fixed on bounds. So, unless F(x) can be evaluated very quickly, the run time will be dominated by the time spent in FUNCT1.

Ideally the problem should be scaled so that at the solution the value of F(x) and the corresponding values of x ,x ,...,x are

```
                                                 1  2      n
         each in the range (-1,+1), and so that at points a unit distance
         away from the solution, F is approximately a unit value greater
         than at the minimum. It is unlikely that the user will be able to
         follow these recommendations very closely, but it is worth trying
         (by guesswork), as sensible scaling will reduce the difficulty of
         the minimization problem, so that E04JAF will take less computer
         time.

         9. Example

         To minimize

                              2         2         4          4
                    F=(x +10x ) +5(x -x ) +(x -2x ) +10(x -x )
                        1    2      3  4     2   3       1  4

         subject to

                                          1<=x <=3
                                              1

                                          -2<=x <=0
                                               2

                                          1<=x <=3,
                                              4

         starting from the initial guess (3, - 1, 0, 1).

         The example program is not reproduced here. The source code for
         all example programs is distributed with the NAG Foundation
         Library software and should be available on-line.

E04MBF(3NAG)      Foundation Library (12/10/92)      E04MBF(3NAG)

     E04 -- Minimizing or Maximizing a Function                 E04MBF
             E04MBF -- NAG Foundation Library Routine Document

     Note: Before using this routine, please read the Users' Note for
     your implementation to check implementation-dependent details.
     The symbol (*) after a NAG routine name denotes a routine that is
     not included in the Foundation Library.

     1. Purpose

     E04MBF is an easy-to-use routine for solving linear programming
     problems, or for finding a feasible point for such problems. It
     is not intended for large sparse problems.

     2. Specification

            SUBROUTINE E04MBF (ITMAX, MSGLVL, N, NCLIN, NCTOTL, NROWA,
           1                   A, BL, BU, CVEC, LINOBJ, X, ISTATE,
           2                   OBJLP, CLAMDA, IWORK, LIWORK, WORK,
           3                   LWORK, IFAIL)
            INTEGER          ITMAX, MSGLVL, N, NCLIN, NCTOTL, NROWA,
           1                 ISTATE(NCTOTL), IWORK(LIWORK), LIWORK,
           2                 LWORK, IFAIL
            DOUBLE PRECISION A(NROWA,N), BL(NCTOTL), BU(NCTOTL), CVEC
           1                 (N), X(N), OBJLP, CLAMDA(NCTOTL), WORK
           2                 (LWORK)
            LOGICAL          LINOBJ

     3. Description

     E04MBF solves linear programming (LP) problems of the form

                      T                    (x )
          Minimize   c x   subject to  l<=(Ax)<=u            (LP)
                   n
          x is in R

     where c is an n element vector and A is an m by n matrix i.e.,
     there are n variables and m general linear constraints. m may be
     zero in which case the LP problem is subject only to bounds on
     the variables. Notice that upper and lower bounds are specified
     for all the variables and constraints. This form allows full
     generality in specifying other types of constraints. For example
```

the ith constraint may be specified as equality by setting $l_i = u_i$.

If certain bounds are not present the associated elements of l or u can be set to special values that will be treated as -infty or +infty.

The routine allows the linear objective function to be omitted in which case a feasible point for the set of constraints is sought.

The user must supply an initial estimate of the solution.

Users who wish to exercise additional control and users with problems whose solution would benefit from additional flexibility should consider using the comprehensive routine E04NAF.

[2] Gill P E, Murray W, Saunders M A and Wright M H (1983) User's Guide for SOL/QPSOL. Report SOL 83-7. Department of Operations Research, Stanford University.

5. Parameters

1: ITMAX -- INTEGER Input

On entry: an upper bound on the number of iterations to be taken. If ITMAX is not positive, then the value 50 is used in place of ITMAX.

2: MSGLVL -- INTEGER Input

On entry: indicates whether or not printout is required at the final solution. When printing occurs the output is on the advisory message channel (see X04ABF). A description of the printed output is given in Section 5.1. The level of printing is determined as follows:

MSGLVL < 0
: No printing.

MSGLVL = 0
: Printing only if an input parameter is incorrect, or if the problem is so ill-conditioned that subsequent overflow is likely. This setting is strongly recommended in preference to MSGLVL < 0.

MSGLVL = 1
: Printing at the solution.

MSGLVL > 1

```
             Values greater than 1 should normally be used only at
             the direction of NAG; such values may generate large
             amounts of printed output.

       3:  N -- INTEGER                                       Input
           On entry: the number n of variables. Constraint: N >= 1.

       4:  NCLIN -- INTEGER                                   Input
           On entry: the number of general linear constraints in the
           problem. Constraint: NCLIN >= 0.

       5:  NCTOTL -- INTEGER                                  Input
           On entry: the value (N+NCLIN).

       6:  NROWA -- INTEGER                                   Input
           On entry:
           the first dimension of the array A as declared in the
           (sub)program from which E04MBF is called.
           Constraint: NROWA >= max(1,NCLIN).

       7:  A(NROWA,N) -- DOUBLE PRECISION array               Input
           On entry: the leading NCLIN by n part of A must contain the
           NCLIN general constraints, with the coefficients of the ith
           constraint in the ith row of A. If NCLIN = 0, then A is not
           referenced.

       8:  BL(NCTOTL) -- DOUBLE PRECISION array               Input
           On entry: the first n elements of BL must contain the lower
           bounds on the n variables, and when NCLIN > 0, the next
           NCLIN elements of BL must contain the lower bounds on the
           NCLIN general linear constraints. To specify a non-existent
           lower bound (l =-infty), set BL(j)<=-1.0E+20.
                         j

       9:  BU(NCTOTL) -- DOUBLE PRECISION array               Input
           On entry: the first n elements of BU must contain the upper
           bounds on the n variables, and when NCLIN > 0, the next
           NCLIN elements of BU must contain the upper bounds on the
           NCLIN general linear constraints. To specify a non-existent
           upper bound (u =+infty), set BU(j)>=1.0E+20. Constraint:
                         j
           BL(j)<=BU(j), for j=1,2,...,NCTOTL.

      10:  CVEC(N) -- DOUBLE PRECISION array                  Input
           On entry: with LINOBJ = .TRUE., CVEC must contain the
           coefficients of the objective function. If LINOBJ = .FALSE.,
           then CVEC is not referenced.

      11:  LINOBJ -- LOGICAL                                  Input
           On entry: indicates whether or not a linear objective
           function is present. If LINOBJ = .TRUE., then the full LP
           problem is solved, but if LINOBJ = .FALSE., only a feasible
           point is found and the array CVEC is not referenced.

      12:  X(N) -- DOUBLE PRECISION array                 Input/Output
           On entry: an estimate of the solution, or of a feasible
           point. Even when LINOBJ = .TRUE. it is not necessary for the
           point supplied in X to be feasible. In the absence of better
           information all elements of X may be set to zero. On exit:
           the solution to the LP problem when LINOBJ = .TRUE., or a
           feasible point when LINOBJ = .FALSE..

           When no feasible point exists (see IFAIL = 1 in Section 6)
           then X contains the point for which the sum of the
           infeasibilities is a minimum. On return with IFAIL = 2, 3 or
           4, X contains the point at which E04MBF terminated.

      13:  ISTATE(NCTOTL) -- INTEGER array                      Output
           On exit: with IFAIL < 5, ISTATE indicates the status of
           every constraint at the final point. The first n elements of
           ISTATE refer to the upper and lower bounds on the variables
           and when NCLIN > 0 the next NCLIN elements refer to the
           general constraints.

           Their meaning is:
           ISTATE(j) Meaning

           -2         The constraint violates its lower bound. This
                     value cannot occur for any element of ISTATE when
                     a feasible point has been found.

           -1         The constraint violates its upper bound. This
                     value cannot occur for any element of ISTATE when
                     a feasible point has been found.

           0          The constraint is not in the working set (is not
                     active) at the final point. Usually this means
                     that the constraint lies strictly between its
                     bounds.

           1          This inequality constraint is in the working set
                     (is active) at its lower bound.

           2          This inequality constraint is in the working set
                     (is active) at its upper bound.

           3          This constraint is included in the working set (is
                     active) as an equality. This value can only occur
                     when BL(j) = BU(j).
```

```
14:  OBJLP -- DOUBLE PRECISION                             Output
     On exit: when LINOBJ = .TRUE., then on successful exit,
     OBJLP contains the value of the objective function at the
     solution, and on exit with IFAIL = 2, 3 or 4, OBJLP contains
     the value of the objective function at the point returned in
     X.

     When LINOBJ = .FALSE., then on successful exit OBJLP will be
     zero and on return with IFAIL = 1, OBJLP contains the
     minimum sum of the infeasibilities corresponding to the
     point returned in X.

15:  CLAMDA(NCTOTL) -- DOUBLE PRECISION array              Output
     On exit: when LINOBJ = .TRUE., then on successful exit, or
     on exit with IFAIL = 2, 3, or 4, CLAMDA contains the
     Lagrange multipliers (reduced costs) for each constraint
     with respect to the working set. The first n components of
     CLAMDA contain the multipliers for the bound constraints on
     the variables and the remaining NCLIN components contain the
     multipliers for the general linear constraints.

     If ISTATE(j) = 0 so that the jth constraint is not in the
     working set then CLAMDA(j) is zero. If X is optimal and
     ISTATE(j) = 1, then CLAMDA(j) should be non-negative, and if
     ISTATE(j) = 2, then CLAMDA(j) should be non-positive.

     When LINOBJ = .FALSE., all NCTOTL elements of CLAMDA are
     returned as zero.

16:  IWORK(LIWORK) -- INTEGER array                     Workspace

17:  LIWORK -- INTEGER                                      Input
     On entry: the length of the array IWORK as declared in the
     (sub)program from which E04MBF is called. Constraint:
     LIWORK>=2*N.

18:  WORK(LWORK) -- DOUBLE PRECISION array              Workspace

19:  LWORK -- INTEGER                                       Input
     On entry: the length of the array WORK as declared in the
     (sub)program from which E04MBF is called. Constraints:
     when N <= NCLIN then
                 2
           LWORK>=2*N +6*N+4*NCLIN+NROWA;

     when 0 <= NCLIN < N then
                         2
           LWORK>=2*(NCLIN+1) +4*NCLIN+6*N+NROWA.

20:  IFAIL -- INTEGER                                Input/Output
```

On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL /=0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit. To suppress the output of an error message when soft failure occurs, set IFAIL to 1.

5.1. Description of the Printed Output

When MSGLVL = 1, then E04MBF will produce output on the advisory message channel (see X04ABF), giving information on the final point. The following describes the printout associated with each variable.

Output	Meaning
VARBL	The name (V) and index j, for j=1,2,...,n, of the variable.
STATE	The state of the variable. (FR if neither bound is in the working set, EQ for a fixed variable, LL if on its lower bound, UL if on its upper bound and TB if held on a temporary bound.) If the value of the variable lies outside the upper or lower bound then STATE will be ++ or -- respectively.
VALUE	The value of the variable at the final iteration.
LOWER BOUND	The lower bound specified for the variable.
UPPER BOUND	The upper bound specified for the variable.
LAGR MULT	The value of the Lagrange multiplier for the associated bound.
RESIDUAL	The difference between the value of the variable and the nearer of its bounds.

For each of the general constraints the printout is as above with refers to the jth element of Ax, except that VARBL is replaced by:

LNCON	The name (L) and index j, for j = 1,2,...,NCLIN of

```
                the constraint.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

Note: when MSGLVL=1 a short description of the error is printed.

IFAIL= 1
     No feasible point could be found. Moving violated
     constraints so that they are satisfied at the point returned
     in X gives the minimum moves necessary to make the LP
     problem feasible.

IFAIL= 2
     The solution to the LP problem is unbounded.

IFAIL= 3
     A total of 50 changes were made to the working set without
     altering x. Cycling is probably occurring. The user should
     consider using E04NAF with MSGLVL >= 5 to monitor constraint
     additions and deletions in order to determine whether or not
     cycling is taking place.

IFAIL= 4
     The limit on the number of iterations has been reached.
     Increase ITMAX or consider using E04NAF to monitor progress.

IFAIL= 5
     An input parameter is invalid. Unless MSGLVL < 0 a message
     will be printed.

IFAILOverflow
     If the printed output before the overflow occurred contains
     a warning about serious ill-conditioning in the working set
     when adding the jth constraint, then either the user should
     try using E04NAF and experiment with the magnitude of FEATOL
     (j) in that routine, or the offending linearly dependent
     constraint (with index j) should be removed from the
     problem.

7. Accuracy

The routine implements a numerically stable active set strategy
and returns solutions that are as accurate as the condition of
the LP problem warrants on the machine.

8. Further Comments

The time taken by each iteration is approximately proportional to
```

$\min(n^2, NCLIN^2)$.

Sensible scaling of the problem is likely to reduce the number of iterations required and make the problem less sensitive to perturbations in the data, thus improving the condition of the LP problem. In the absence of better information it is usually sensible to make the Euclidean lengths of each constraint of comparable magnitude. See Gill et al [1] for further information and advice.

Note that the routine allows constraints to be violated by an absolute tolerance equal to the machine precision (see X02AJF(*))

9. Example

To minimize the function

$$-0.02x_1 -0.2x_2 -0.2x_3 -0.2x_4 -0.2x_5 +0.04x_6 +0.04x_7$$

subject to the bounds

$$\begin{aligned}
-0.01 &\le x_1 \le 0.01\\
-0.1 &\le x_2 \le 0.15,\\
-0.01 &\le x_3 \le 0.03,\\
-0.04 &\le x_4 \le 0.02,\\
-0.1 &\le x_5 \le 0.05,\\
-0.01 &\le x_6\\
-0.01 &\le x_7
\end{aligned}$$

and the general constraints

$$x_1 +x_2 +x_3 +x_4 +x_5 +x_6 +x_7 =-0.13$$

$$0.15x_1 +0.04x_2 +0.02x_3 +0.04x_4 +0.02x_5 +0.01x_6 +0.03x_7 \le -0.0049$$

$$0.03x_1 +0.05x_2 +0.08x_3 +0.02x_4 +0.06x_5 +0.01x_6 \le -0.0064$$

$$0.02x +0.04x +0.01x +0.02x +0.02x \le -0.0037$$

```
                   1      2      3      4      5

                     0.02x +0.03x +0.01x <=-0.0012
                          1      2      5

          -0.0992<=0.70x +0.75x +0.80x +0.75x +0.80x +0.97x
                        1      2      3      4      5      6

         -0.003<=0.02x +0.06x +0.08x +0.12x +0.02x +0.01x +0.97x <=0.002
                     1      2      3      4      5      6      7

          The initial point, which is infeasible, is

                                                       T
                x =(-0.01, -0.03, 0.0, -0.01, -0.1, 0.02, 0.01) .
                 0

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

     E04NAF(3NAG)      Foundation Library (12/10/92)      E04NAF(3NAG)

          E04 -- Minimizing or Maximizing a Function                 E04NAF
                  E04NAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
```

not included in the Foundation Library.

1. Purpose

E04NAF is a comprehensive routine for solving quadratic programming (QP) or linear programming (LP) problems. It is not intended for large sparse problems.

2. Specification

```
       SUBROUTINE E04NAF (ITMAX, MSGLVL, N, NCLIN, NCTOTL, NROWA,
      1                   NROWH, NCOLH, BIGBND, A, BL, BU, CVEC,
      2                   FEATOL, HESS, QPHESS, COLD, LP, ORTHOG,
      3                   X, ISTATE, ITER, OBJ, CLAMDA, IWORK,
      4                   LIWORK, WORK, LWORK, IFAIL)
       INTEGER          ITMAX, MSGLVL, N, NCLIN, NCTOTL, NROWA,
      1                 NROWH, NCOLH, ISTATE(NCTOTL), ITER, IWORK
      2                 (LIWORK), LIWORK, LWORK, IFAIL
       DOUBLE PRECISION BIGBND, A(NROWA,N), BL(NCTOTL),
      1                 BU(NCTOTL), CVEC(N), FEATOL(NCTOTL), HESS
      2                 (NROWH,NCOLH), X(N), OBJ, CLAMDA(NCTOTL),
      3                 WORK(LWORK)
       LOGICAL          COLD, LP, ORTHOG
       EXTERNAL         QPHESS
```

3. Description

E04NAF is essentially identical to the subroutine SOL/QPSOL described in Gill et al [1].

E04NAF is designed to solve the quadratic programming (QP) problem - the minimization of a quadratic function subject to a set of linear constraints on the variables. The problem is assumed to be stated in the following form:

$$\text{Minimize}\quad c^T x + \frac{1}{2} x^T H x \quad \text{subject to}\quad l \le \begin{pmatrix} x \\ Ax \end{pmatrix} \le u\ , \qquad (1)$$

where c is a constant n-vector and H is a constant n by n symmetric matrix; note that H is the Hessian matrix (matrix of second partial derivatives) of the quadratic objective function. The matrix A is m by n, where m may be zero; A is treated as a dense matrix.

The constraints involving A will be called the general constraints. Note that upper and lower bounds are specified for all the variables and for all the general constraints. The form of (1) allows full generality in specifying other types of constraints. In particular, an equality constraint is specified by setting $l_i=u_i$. If certain bounds are not present, the associated elements of l or u can be set to special values that will be treated as -infty or +infty.

The user must supply an initial estimate of the solution to (1), and a subroutine that computes the product Hx for any given vector x. If H is positive-definite or positive semi-definite, E04NAF will obtain a global minimum; otherwise, the solution obtained will be a local minimum (which may or may not be a global minimum). If H is defined as the zero matrix, E04NAF will solve the resulting linear programming (LP) problem; however, this can be accomplished more efficiently by setting a logical variable in the call of the routine (see the parameter LP in Section 5).

E04NAF allows the user to provide the indices of the constraints that are believed to be exactly satisfied at the solution. This facility, known as a warm start, can lead to significant savings in computational effort when solving a sequence of related problems.

The method has two distinct phases. In the first (the LP phase), an iterative procedure is carried out to determine a feasible point. In this context, feasibility is defined by a user-provided array FEATOL; the jth constraint is considered satisfied if its violation does not exceed FEATOL(j). The second phase (the QP phase) generates a sequence of feasible iterates in order to minimize the quadratic objective function. In both phases, a subset of the constraints - called the working set - is used to define the search direction at each iteration; typically, the working set includes constraints that are satisfied to within the corresponding tolerances in the FEATOL array.

We now briefly describe a typical iteration in the QP phase. Let x_k denote the estimate of the solution at the kth iteration; the next iterate is defined by

$$x_{k+1}=x_k+(alpha)_k p_k$$

where p_k is an n-dimensional search direction and $(alpha)_k$ is a scalar step length. Assume that the working (active) set contains t_k linearly independent constraints, and let C_k denote the matrix of coefficients of the bounds and general constraints in the current working set.

Let Z_k denote a matrix whose columns form a basis for the null space of C_k, so that $C_k Z_k = 0$. (Note that Z_k has n_z columns, where $n_z = n - t_k$.) The vector $Z_k^T (c + Hx_k)$ is called the projected gradient at x_k. If the projected gradient is zero at x_k (i.e., x_k is a constrained stationary point in the subspace defined by Z_k), Lagrange multipliers $(\lambda)_k$ are defined as the solution of the compatible overdetermined system

$$C_k^T (\lambda)_k = c + Hx_k \qquad (2)$$

The Lagrange multiplier (λ) corresponding to an inequality constraint in the working set is said to be optimal if $(\lambda) <= 0$ when the associated constraint is at its upper bound, or if $(\lambda) >= 0$ when the associated constraint is at its lower bound. If a multiplier is non-optimal, the objective function can be reduced by deleting the corresponding constraint (with index JDEL, see Section 5.1) from the working set.

If the projected gradient at x_k is non-zero, the search direction p_k is defined as

$$p_k = Z_k p_z \qquad (3)$$

where p_z is an n_z-vector. In effect, the constraints in the working set are treated as equalities, by constraining p_k to lie within the subspace of vectors orthogonal to the rows of C_k. This definition ensures that $C_k p_k = 0$, and hence the values of the constraints in the working set are not altered by any move along p_k.

The vector p_z is obtained by solving the equations

$$Z_k^T H Z_k p_z = -Z_k^T (c+Hx_k) \qquad (4)$$

(The matrix $Z_k^T H Z_k$ is called the projected Hessian matrix.) If the projected Hessian is positive-definite, the vector defined by (3) and (4) is the step to the minimum of the quadratic function in the subspace defined by Z_k.

If the projected Hessian is positive-definite and x_k+p_k is feasible, $(alpha)_k$ will be taken as unity. In this case, the projected gradient at x_{k+1} will be zero (see NORM ZTG in Section 5.1), and Lagrange multipliers can be computed (see Gill et al [2]). Otherwise, $(alpha)_k$ is set to the step to the 'nearest' constraint (with index JADD, see Section 5.1), which is added to the working set at the next iteration.

The matrix Z_k is obtained from the TQ factorization of C_k, in which C_k is represented as

$$C_k Q = (0 \; T_k) \qquad (5)$$

where T_k is reverse-triangular. It follows from (5) that Z_k may be taken as the first n_z columns of Q. If the projected Hessian is positive-definite, (3) is solved using the Cholesky factorization

$$Z_k^T H Z_k = R_k^T R_k$$

where R_k is upper triangular. These factorizations are updated as constraints enter or leave the working set (see Gill et al [2] for further details).

An important feature of E04NAF is the treatment of indefiniteness in the projected Hessian. If the projected Hessian is positive-definite, it may become indefinite only when a constraint is deleted from the working set. In this case, a temporary modification (of magnitude HESS MOD, see Section 5.1) is added to the last diagonal element of the Cholesky factor. Once a modification has occurred, no further constraints are deleted from the working set until enough constraints have been added so that the projected Hessian is again positive-definite. If equation (1) has a finite solution, a move along the direction obtained by solving (4) with the modified Cholesky factor must encounter a constraint that is not already in the working set.

In order to resolve indefiniteness in this way, we must ensure that the projected Hessian is positive-definite at the first iterate in the QP phase. Given the n_z by n_z projected Hessian, a step-wise Cholesky factorization is performed with symmetric interchanges (and corresponding rearrangement of the columns of Z), terminating if the next step would cause the matrix to become indefinite. This determines the largest possible positive-definite principal sub-matrix of the (permuted) projected Hessian. If n_R steps of the Cholesky factorization have been successfully completed, the relevant projected Hessian is an n_R by n_R positive-definite matrix $Z_R^T HZ_R$, where Z_R comprises the first n_R columns of Z. The quadratic function will subsequently be minimized within subspaces of reduced dimension until the full projected Hessian is positive-definite.

If a linear program is being solved and there are fewer general constraints than variables, the method moves from one vertex to another while minimizing the objective function. When necessary, an initial vertex is defined by temporarily fixing some of the variables at their initial values.

Several strategies are used to control ill-conditioning in the working set. One such strategy is associated with the FEATOL array. Allowing the jth constraint to be violated by as much as FEATOL(j) often provides a choice of constraints that could be added to the working set. When a choice exists, the decision is based on the conditioning of the working set. Negative steps are occasionally permitted, since x_k may violate the constraint to be added.

5. Parameters

1: ITMAX -- INTEGER Input
On entry: an upper bound on the number of iterations to be taken during the LP phase or the QP phase. If ITMAX is not positive, then the value 50 is used in place of ITMAX.

2: MSGLVL -- INTEGER Input
On entry: MSGLVL must indicate the amount of intermediate output desired (see Section 5.1 for a description of the printed output). All output is written to the current advisory message unit (see X04ABF). For MSGLVL >= 10, each level includes the printout for all lower levels.

Value	Definition
<0	No printing.
0	Printing only if an input parameter is incorrect, or if the working set is so ill-conditioned that subsequent overflow is likely. This setting is strongly recommended in preference to MSGLVL < 0.
1	The final solution only.
5	One brief line of output for each constraint addition or deletion (no printout of the final solution).
>=10	The final solution and one brief line of output for each constraint addition or deletion.
>=15	At each iteration, X, ISTATE, and the indices of the free variables (i.e.,the variables not currently held on a bound).
>=20	At each iteration, the Lagrange multiplier estimates and the general constraint values.

```
>=30    At each iteration, the diagonal elements of the
        matrix T associated with the TQ factorization of the
        working set, and the diagonal elements of the
        Cholesky factor R of the projected Hessian.

>=80    Debug printout.

99      The arrays CVEC and HESS.
```

```
 3:  N -- INTEGER                                          Input
     On entry: the number, n, of variables. Constraint: N >= 1.

 4:  NCLIN -- INTEGER                                      Input
     On entry: the number of general linear constraints in the
     problem. Constraint: NCLIN >= 0.

 5:  NCTOTL -- INTEGER                                     Input
     On entry: the value (N+NCLIN).

 6:  NROWA -- INTEGER                                      Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which E04NAF is called.
     Constraint: NROWA >= max(1,NCLIN).

 7:  NROWH -- INTEGER                                      Input
     On entry: the first dimension of the array HESS as declared
     in the (sub)program from which E04NAF is called.
     Constraint: NROWH >= 1.

 8:  NCOLH -- INTEGER                                      Input
     On entry: the column dimension of the array HESS as declared
     in the (sub)program from which E04NAF is called.
     Constraint: NCOLH >= 1.

 9:  BIGBND -- DOUBLE PRECISION                            Input
     On entry: BIGBND must denote an 'infinite' component of l
     and u. Any upper bound greater than or equal to BIGBND will
     be regarded as plus infinity, and a lower bound less than or
     equal to -BIGBND will be regarded as minus infinity.
     Constraint: BIGBND > 0.0.

10:  A(NROWA,N) -- DOUBLE PRECISION array                  Input
     On entry: the leading NCLIN by n part of A must contain the
     NCLIN general constraints, with the ith constraint in the i
     th row of A. If NCLIN = 0, then A is not referenced.

11:  BL(NCTOTL) -- DOUBLE PRECISION array                  Input
     On entry: the lower bounds for all the constraints, in the
     following order. The first n elements of BL must contain the
     lower bounds on the variables. If NCLIN > 0, the next NCLIN
     elements of BL must contain the lower bounds for the general
     linear constraints. To specify a non-existent lower bound
     (i.e., l =-infty), the value used must satisfy BL(j)<=-
             j
     BIGBND To specify the jth constraint as an equality, the
     user must set BL(j) = BU(j). Constraint: BL(j) <= BU(j),
     j=1,2,...,NCTOTL.

 12: BU(NCTOTL) -- DOUBLE PRECISION array                   Input
     On entry: the upper bounds for all the constraints, in the
     following order. The first n elements of BU must contain the
     upper bounds on the variables. If NCLIN > 0, the next NCLIN
     elements of BU must contain the upper bounds for the general
     linear constraints. To specify a non-existent upper bound
     (i.e., u =+infty), the value used must satisfy BU(j) >=
             j
     BIGBND. To specify the jth constraint as an equality, the
     user must set BU(j) = BL(j). Constraint: BU(j) >= BL(j),
     j=1,2,...,NCTOTL.

 13: CVEC(N) -- DOUBLE PRECISION array                      Input
     On entry: the coefficients of the linear term of the
     objective function (the vector c in equation  (1)).

 14: FEATOL(NCTOTL) -- DOUBLE PRECISION array               Input
     On entry: a set of positive tolerances that define the
     maximum permissible absolute violation in each constraint in
     order for a point to be considered feasible, i.e., if the
     violation in constraint j is less than FEATOL(j), the point
     is considered to be feasible with respect to the jth
     constraint. The ordering of the elements of FEATOL is the
     same as that described above for BL.

     The elements of FEATOL should not be too small and a warning
     message will be printed on the current advisory message
     channel if any element of FEATOL is less than the machine
     precision (see X02AJF(*)). As the elements of FEATOL
     increase, the algorithm is less likely to encounter
     difficulties with ill-conditioning and degeneracy. However,
     larger values of FEATOL(j) mean that constraint j could be
     violated by a significant amount. It is recommended that
     FEATOL(j) be set to a value equal to the largest acceptable
     violation for constraint j. For example, if the data
     defining the constraints are of order unity and are correct
     to about 6 decimal digits, it would be appropriate to choose
                    -6
     FEATOL(j) as 10   for all relevant j. Often the square root
     of the machine precision is a reasonable choice if the
     constraint is well scaled.
```

```
15:  HESS(NROWH,NCOLH) -- DOUBLE PRECISION array            Input
     On entry: HESS may be used to store the Hessian matrix H of
     equation (1) if desired. HESS is accessed only by the
     subroutine QPHESS and is not accessed if LP = .TRUE.. Refer
     to the specification of QPHESS (below) for further details
     of how HESS may be used to pass data to QPHESS.

16:  QPHESS -- SUBROUTINE, supplied by the user.
                                                 External Procedure
     QPHESS must define the product of the Hessian matrix H and a
     vector x. The elements of H need not be defined explicitly.
     QPHESS is not accessed if LP is set to .TRUE. and in this
     case QPHESS may be the dummy routine E04NAN. (E04NAN is
     included in the NAG Foundation Library and so need not be
     supplied by the user. Its name may be implementation-
     dependent: see the Users' Note for your implementation for
     details.)

     Its specification is:

            SUBROUTINE QPHESS (N, NROWH, NCOLH, JTHCOL,
           1                   HESS, X, HX)
            INTEGER          N, NROWH, NCOLH, JTHCOL
            DOUBLE PRECISION HESS(NROWH,NCOLH), X(N), HX(N)

      1:  N -- INTEGER                                      Input
          On entry: the number n of variables.

      2:  NROWH -- INTEGER                                  Input
          On entry: the row dimension of the array HESS.

      3:  NCOLH -- INTEGER                                  Input
          On entry: the column dimension of the array HESS.

      4:  JTHCOL -- INTEGER                                 Input
          The input parameter JTHCOL is included to allow
          flexibility for the user in the special situation when
          x is the jth co-ordinate vector (i.e.,the jth column of
          the identity matrix). This may be of interest because
          the product Hx is then the jth column of H, which can
          sometimes be computed very efficiently. The user may
          code QPHESS to take advantage of this case. On entry:
          if JTHCOL = j, where j>0, HX must contain column JTHCOL
          of H, and hence special code may be included in QPHESS
          to test JTHCOL if desired. However, special code is not
          necessary, since the vector x always contains column
          JTHCOL of the identity matrix whenever QPHESS is called
          with JTHCOL > 0.
      5:  HESS(NROWH,NCOLH) -- DOUBLE PRECISION array       Input
          On entry: the Hessian matrix H.

          In some cases, it may be desirable to use a one-
          dimensional array to transmit data or workspace to
          QPHESS; HESS should then be declared with dimension
          (NROWH) in the (sub)program from which E04NAF is called
          and the parameter NCOLH must be 1.

          In other situations, it may be desirable to compute Hx
          without accessing HESS - for example, if H is sparse or
          has special structure. (This is illustrated in the
          subroutine QPHES1 in the example program in Section 9.)
          The parameters HESS, NROWH and NCOLH may then refer to
          any convenient array.

          When MSGLVL = 99, the (possibly undefined) contents of
          HESS will be printed, except if NROWH and NCOLH are
          both 1. Also printed are the results of calling QPHESS
          with JTHCOL = 1,2,...,n.

      6:  X(N) -- DOUBLE PRECISION array                    Input
          On entry: the vector x.

      7:  HX(N) -- DOUBLE PRECISION array                  Output
          On exit: HX must contain the product Hx.
     QPHESS must be declared as EXTERNAL in the (sub)program
     from which E04NAF is called. Parameters denoted as
     Input must not be changed by this procedure.

17: COLD -- LOGICAL                                        Input
     On entry: COLD must indicate whether the user has specified
     an initial estimate of the active set of constraints. If
     COLD is set to .TRUE., the initial working set is determined
     by E04NAF. If COLD is set to .FALSE. (a 'warm start'), the
     user must define the ISTATE array which gives the status of
     each constraint with respect to the working set. E04NAF will
     override the user's specification of ISTATE if necessary, so
     that a poor choice of working set will not cause a fatal
     error.

     The warm start option is particularly useful when E04NAF is
     called repeatedly to solve related problems.

18: LP -- LOGICAL                                          Input
     On entry: if LP = .FALSE., E04NAF will solve the specified
     quadratic programming problem. If LP = .TRUE., E04NAF will
     treat H as zero and solve the resulting linear programming
     problem; in this case, the parameters HESS and QPHESS will
     not be referenced.
```

```
19:  ORTHOG -- LOGICAL                                      Input
     On entry: ORTHOG must indicate whether orthogonal
     transformations are to be used in computing and updating the
     TQ factorization of the working set
                              A Q=(0 T),
                               s
     where A  is a sub-matrix of A and T is reverse-triangular.
            s
     If ORTHOG = .TRUE., the TQ factorization is computed using
     Householder reflections and plane rotations, and the matrix
     Q is orthogonal. If ORTHOG = .FALSE., stabilized elementary
     transformations are used to maintain the factorization, and
     Q is not orthogonal. A rule of thumb in making the choice is
     that orthogonal transformations require more work, but
     provide greater numerical stability. Thus, we recommend
     setting ORTHOG to .TRUE. if the problem is reasonably small
     or the active set is ill-conditioned. Otherwise, setting
     ORTHOG to .FALSE. will often lead to a reduction in solution
     time with negligible loss of reliability.

20:  X(N) -- DOUBLE PRECISION array                  Input/Output
     On entry: an estimate of the solution. In the absence of
     better information all elements of X may be set to zero. On
     exit: from E04NAF, X contains the best estimate of the
     solution.

21:  ISTATE(NCTOTL) -- INTEGER array                 Input/Output
     On entry: with COLD as .FALSE., ISTATE must indicate the
     status of every constraint with respect to the working set.
     The ordering of ISTATE is as follows; the first n elements
     of ISTATE refer to the upper and lower bounds on the
     variables and elements n+1 through n + NCLIN refer to the
     upper and lower bounds on Ax. The significance of each
     possible value of ISTATE(j) is as follows:
     ISTATE(j) Meaning

     -2        The constraint violates its lower bound by more
               than FEATOL(j). This value of ISTATE cannot occur
               after a feasible point has been found.

     -1        The constraint violates its upper bound by more
               than FEATOL(j). This value of ISTATE cannot occur
               after a feasible point has been found.

     0         The constraint is not in the working set. Usually,
               this means that the constraint lies strictly
               between its bounds.

     1         This inequality constraint is included in the
```

```
                 working set at its lower bound. The value of the
                 constraint is within FEATOL(j) of its lower bound.

          2      This inequality constraint is included in the
                 working set at its upper bound. The value of the
                 constraint is within FEATOL(j) of its upper bound.

          3      The constraint is included in the working set as
                 an equality. This value of ISTATE can occur only
                 when BL(j) = BU(j). The corresponding constraint
                 is within FEATOL(j) of its required value.
          If COLD = .TRUE., ISTATE need not be set by the user.
          However, when COLD = .FALSE., every element of ISTATE must
          be set to one of the values given above to define a
          suggested initial working set (which will be changed by
          E04NAF if necessary). The most likely values are:
          ISTATE(j) Meaning

          0      The corresponding constraint should not be in the
                 initial working set.

          1      The constraint should be in the initial working
                 set at its lower bound.

          2      The constraint should be in the initial working
                 set at its upper bound.

          3      The constraint should be in the initial working
                 set as an equality. This value must not be
                 specified unless BL(j) = BU(j). The values 1, 2 or
                 3 all have the same effect when BL(j) = BU(j).
          Note that if E04NAF has been called previously with the same
          values of N and NCLIN, ISTATE already contains satisfactory
          values. On exit: when E04NAF exits with IFAIL set to 0, 1 or
          3, the values in the array ISTATE indicate the status of the
          constraints in the active set at the solution. Otherwise,
          ISTATE indicates the composition of the working set at the
          final iterate.

     22:  ITER -- INTEGER                                        Output
          On exit: the number of iterations performed in either the LP
          phase or the QP phase, whichever was last entered.

          Note that ITER is reset to zero after the LP phase.

     23:  OBJ -- DOUBLE PRECISION                                Output
          On exit: the value of the quadratic objective function at x
          if x is feasible (IFAIL <= 5), or the sum of infeasibilities
          at x otherwise (6 <= IFAIL <= 8).
```

```
24:  CLAMDA(NCTOTL) -- DOUBLE PRECISION array             Output
     On exit: the values of the Lagrange multiplier for each
     constraint with respect to the current working set. The
     ordering of CLAMDA is as follows; the first n components
     contain the multipliers for the bound constraints on the
     variables, and the remaining components contain the
     multipliers for the general linear constraints. If ISTATE(j)
     = 0 (i.e.,constraint j is not in the working set), CLAMDA(j)
     is zero. If x is optimal and ISTATE(j) = 1, CLAMDA(j) should
     be non-negative; if ISTATE(j) = 2, CLAMDA(j) should be non-
     positive.

25:  IWORK(LIWORK) -- INTEGER array                     Workspace

26:  LIWORK -- INTEGER                                      Input
     On entry:
     the dimension of the array IWORK as declared in the
     (sub)program from which E04NAF is called.
     Constraint: LIWORK>=2*N.

27:  WORK(LWORK) -- DOUBLE PRECISION array              Workspace

28:  LWORK -- INTEGER                                       Input
     On entry:
     the dimension of the array WORK as declared in the
     (sub)program from which E04NAF is called.
     Constrai if LP = .FALSE. or NCLIN >= N then
     nts:             2
              LWORK>=2*N +4*N*NCLIN+NROWA.

              if LP = .TRUE. and NCLIN < N then
                                   2
              LWORK>=2*(NCLIN+1) +4*N+2*NCLIN+NROWA.
     If MSGLVL > 0, the amount of workspace provided and the
     amount of workspace required are output on the current
     advisory message unit (as defined by X04ABF). As an
     alternative to computing LWORK from the formula given above,
     the user may prefer to obtain an appropriate value from the
     output of a preliminary run with a positive value of MSGLVL
     and LWORK set to 1 (E04NAF will then terminate with IFAIL =
     9).

29:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. Users who are
     unfamiliar with this parameter should refer to the Essential
     Introduction for details.

     On exit: IFAIL = 0 unless the routine detects an error or
     gives a warning (see Section 6).
```

For this routine, because the values of output parameters may be useful even if IFAIL /=0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit. To suppress the output of an error message when soft failure occurs, set IFAIL to 1.

IFAIL contains zero on exit if x is a strong local minimum. i.e., the projected gradient is neglible, the Lagrange multipliers are optimal, and the projected Hessian is positive-definite. In some cases, a zero value of IFAIL means that x is a global minimum (e.g. when the Hessian matrix is positive-definite).

5.1. Description of the Printed Output

When MSGLVL >= 5, a line of output is produced for every change in the working set (thus, several lines may be printed during a single iteration).

To aid interpretation of the printed results, we mention the convention for numbering the constraints: indices 1 through to n refer to the bounds on the variables, and when NCLIN > 0 indices n+1 through to n + NCLIN refer to the general constraints. When the status of a constraint changes, the index of the constraint is printed, along with the designation L (lower bound), U (upper bound) or E (equality).

In the LP phase, the printout includes the following:

ITN	is the iteration count.
JDEL	is the index of the constraint deleted from the working set. If JDEL is zero, no constraint was deleted.
JADD	is the index of the constraint added to the working set. If JADD is zero, no constraint was added.
STEP	is the step taken along the computed search direction.
COND T	is a lower bound on the condition number of the matrix of predicted active constraints.
NUMINF	is the number of violated constraints (infeasibilities).
SUMINF	is a weighted sum of the magnitudes of the

constraint violations.

LPOBJ	is the value of the linear objective function $c^T x$. It is printed only if LP = .TRUE..

During the QP phase, the printout includes the following:

ITN	is the iteration count (reset to zero after the LP phase).
JDEL	is the index of the constraint deleted from the working set. If JDEL is zero, no constraint was deleted.
JADD	is the index of the constraint added to the working set. If JADD is zero, no constraint was added.
STEP	is the step (alpha)$_k$ taken along the direction of search (if STEP is 1.0, the current point is a minimum in the subspace defined by the current working set).
NHESS	is the number of calls to subroutine QPHESS.
OBJECTIVE	is the value of the quadratic objective function.
NCOLZ	is the number of columns of Z (see Section 3). In general, it is the dimension of the subspace in which the quadratic is currently being minimized.
NORM GFREE	is the Euclidean norm of the gradient of the objective function with respect to the free variables, i.e. variables not currently held at a bound (NORM GFREE is not printed if ORTHOG = . FALSE.). In some cases, the objective function and gradient are updated rather than recomputed. If so, this entry will be -- to indicate that the gradient with respect to the free variables has not been computed.
NORM QTG	is a weighted norm of the gradient of the objective function with respect to the free variables (NORM QTG is not printed if ORTHOG = . TRUE.). In some cases, the objective function and gradient are updated rather than recomputed. If so, this entry will be -- to indicate that the gradient with respect to the free variables has

	not been computed.
NORM ZTG	is the Euclidean norm of the projected gradient (see Section 3).
COND T	is a lower bound on the condition number of the matrix of constraints in the working set.
COND ZHZ	is a lower bound on the condition number of the projected Hessian matrix.
HESS MOD	is the correction added to the diagonal of the projected Hessian to ensure that a satisfactory Cholesky factorization exists (see Section 3). When the projected Hessian is sufficiently positive-definite, HESS MOD will be zero.

When MSGLVL = 1 or MSGLVL >= 10, the summary printout at the end of execution of E04NAF includes a listing of the status of every constraint. Note that default names are assigned to all variables and constraints.

The following describes the printout for each variable.

VARBL	is the name (V) and index j, j=1,2,...,n, of the variable.
STATE	gives the state of the variable (FR if neither bound is in the working set, EQ if a fixed variable, LL if on its lower bound, UL if on its upper bound, TB if held on a temporary bound). If VALUE lies outside the upper or lower bounds by more than FEATOL(j), STATE will be ++ or -- respectively.
VALUE	is the value of the variable at the final iteration.
LOWER BOUND	is the lower bound specified for the variable.
UPPER BOUND	is the upper bound specified for the variable.
LAGR MULT	is the value of the Lagrange multiplier for the associated bound constraint. This will be zero if STATE is FR. If x is optimal and STATE is LL, the multiplier should be non-negative; if STATE is UL, the multiplier should be non-positive.
RESIDUAL	is the difference between the variable and the nearer of its bounds BL(j) and BU(j).

For each of the general constraints the printout is as above with refers to the jth element of Ax, except that VARBL is replaced by

```
LNCON          The name (L) and index j, j=1,2,...,NCLIN, of the
               constraint.
```

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

IFAIL= 1
x is a weak local minimum (the projected gradient is negligible, the Lagrange multipliers are optimal, but the projected Hessian is only semi-definite). This means that the solution is not unique.

IFAIL= 2
The solution appears to be unbounded, i.e., the quadratic function is unbounded below in the feasible region. This value of IFAIL occurs when a step of infinity would have to be taken in order to continue the algorithm.

IFAIL= 3
x appears to be a local minimum, but optimality cannot be verified because some of the Lagrange multipliers are very small in magnitude.

E04NAF has probably found a solution. However, the presence of very small Lagrange multipliers means that the predicted active set may be incorrect, or that x may be only a constrained stationary point rather than a local minimum. The method in E04NAF is not guaranteed to find the correct active set when there are very small multipliers. E04NAF attempts to delete constraints with zero multipliers, but this does not necessarily resolve the issue. The determination of the correct active set is a combinatorial problem that may require an extremely large amount of time. The occurrence of small multipliers often (but not always) indicates that there are redundant constraints.

IFAIL= 4
The iterates of the QP phase could be cycling, since a total of 50 changes were made to the working set without altering x.

This value will occur if 50 iterations are performed in the QP phase without changing x. The user should check the printed output for a repeated pattern of constraint deletions and additions. If a sequence of constraint changes

```
         is being repeated, the iterates are probably cycling.
         (E04NAF  does not contain a method that is guaranteed to
         avoid cycling, which would be combinatorial in nature.)
         Cycling may occur in two circumstances: at a constrained
         stationary point where there are some small or zero Lagrange
         multipliers (see the discussion of IFAIL = 3); or at a point
         (usually a vertex) where the constraints that are satisfied
         exactly are nearly linearly dependent. In the latter case,
         the user has the option of identifying the offending
         dependent constraints and removing them from the problem, or
         restarting the run with larger values of FEATOL for nearly
         dependent constraints. If E04NAF terminates with IFAIL = 4,
         but no suspicious pattern of constraint changes can be
         observed, it may be worthwhile to restart with the final x
         (with or without the warm start option).

    IFAIL= 5
         The limit of ITMAX iterations was reached in the QP phase
         before normal termination occurred.

         The value of ITMAX may be too small. If the method appears
         to be making progress (e.g. the objective function is being
         satisfactorily reduced), increase ITMAX and rerun E04NAF
         (possibly using the warm start facility to specify the
         initial working set). If ITMAX is already large, but some of
         the constraints could be nearly linearly dependent, check
         the output for a repeated pattern of constraints entering
         and leaving the working set. (Near-dependencies are often
         indicated by wide variations in size in the diagonal
         elements of the T matrix, which will be printed if MSGLVL >=
         30.) In this case, the algorithm could be cycling (see the
         comments for IFAIL = 4).

    IFAIL= 6
         The LP phase terminated without finding a feasible point,
         and hence it is not possible to satisfy all the constraints
         to within the tolerances specified by the FEATOL array. In
         this case, the final iterate will reveal values for which
         there will be a feasible point (e.g. a feasible point will
         exist if the feasibility tolerance for each violated
         constraint exceeds its RESIDUAL at the final point). The
         modified problem (with altered values in FEATOL) may then be
         solved using a warm start.

         The user should check that there are no constraint
         redundancies. If the data for the jth constraint are
         accurate only to the absolute precision (delta), the user
         should ensure that the value of FEATOL(j) is greater than
         (delta). For example, if all elements of A are of order
         unity and are accurate only to three decimal places, every
```

component of FEATOL should be at least 10^{-3}.

IFAIL= 7
The iterates may be cycling during the LP phase; see the comments above under IFAIL = 4.

IFAIL= 8
The limit of ITMAX iterations was reached during the LP phase. See comments above under IFAIL = 5.

IFAIL= 9
An input parameter is invalid.

Overflow
If the printed output before the overflow error contains a warning about serious ill-conditioning in the working set when adding the jth constraint, it may be possible to avoid the difficulty by increasing the magnitude of FEATOL(j) and rerunning the program. If the message recurs even after this change, the offending linearly dependent constraint (with index j) must be removed from the problem. If a warning message did not precede the fatal overflow, the user should contact NAG.

7. Accuracy

The routine implements a numerically stable active set strategy and returns solutions that are as accurate as the condition of the QP problem warrants on the machine.

8. Further Comments

The number of iterations depends upon factors such as the number of variables and the distances of the starting point from the solution. The number of operations performed per iteration is roughly proportional to $(NFREE)^2$, where NFREE (NFREE<=n) is the number of variables fixed on their upper or lower bounds.

Sensible scaling of the problem is likely to reduce the number of iterations required and make the problem less sensitive to perturbations in the data, thus improving the condition of the QP problem. See the Chapter Introduction and Gill et al [1] for further information and advice.

9. Example

To minimize the function $c^Tx+\frac{1}{2}x^THx$, where

```
                                  2

                                                             T
                   c=[-0.02,-0.2,-0.2,-0.2,-0.2,0.04,0.04]

                              [2 0 0 0 0  0  0]
                              [0 2 0 0 0  0  0]
                              [0 0 2 2 0  0  0]
                            H=[0 0 2 2 0  0  0]
                              [0 0 0 0 2  0  0]
                              [0 0 0 0 0 -2 -2]
                              [0 0 0 0 0 -2 -2]

        E04 -- Minimizing or Maximizing a Function                E04UCF
                E04UCF -- NAG Foundation Library Routine Document

        Note: Before using this routine, please read the Users' Note for
        your implementation to check implementation-dependent details.
        The symbol (*) after a NAG routine name denotes a routine that is
        not included in the Foundation Library.

        Note for users via the Axiom system: the interface to this routine
        has been enhanced for use with Axiom and is slightly different to
        that offered in the standard version of the Foundation Library.  In
```

particular, the optional parameters of the NAG routine are now included in the parameter list. These are described in section 5.1.2, below.

1. Purpose

E04UCF is designed to minimize an arbitrary smooth function subject to constraints, which may include simple bounds on the variables, linear constraints and smooth nonlinear constraints. (E04UCF may be used for unconstrained, bound-constrained and linearly constrained optimization.) The user must provide subroutines that define the objective and constraint functions and as many of their first partial derivatives as possible. Unspecified derivatives are approximated by finite differences. All matrices are treated as dense, and hence E04UCF is not intended for large sparse problems.

E04UCF uses a sequential quadratic programming (SQP) algorithm in which the search direction is the solution of a quadratic programming (QP) problem. The algorithm treats bounds, linear constraints and nonlinear constraints separately.

2. Specification

```
       SUBROUTINE E04UCF (N, NCLIN, NCNLN, NROWA, NROWJ, NROWR,

3. Description

E04UCF is designed to solve the nonlinear programming problem --

the minimization of a smooth nonlinear function subject to a set of constraints on the variables. The problem is assumed to be stated in the following form:

$$\text{Minimize}_{x \text{ is in } R^n} \quad F(x) \quad \text{subject to} \quad l \le \begin{Bmatrix} x \\ A_L x \\ c(x) \end{Bmatrix} \le u, \qquad (1)$$

where F(x), the objective function, is a nonlinear function, A_L is an n_L by n constant matrix, and c(x) is an n_N element vector of nonlinear constraint functions. (The matrix A_L and the vector c(x) may be empty.) The objective function and the constraint functions are assumed to be smooth, i.e., at least twice-continuously differentiable. (The method of E04UCF will usually solve (1) if there are only isolated discontinuities away from the solution.)

This routine is essentially identical to the subroutine SOL/NPSOL described in Gill et al [8].

Note that upper and lower bounds are specified for all the variables and for all the constraints.

An equality constraint can be specified by setting $l_i=u_i$. If certain bounds are not present, the associated elements of l or u can be set to special values that will be treated as -infty or +infty.

If there are no nonlinear constraints in (1) and F is linear or quadratic then one of E04MBF, E04NAF or E04NCF(*) will generally be more efficient. If the problem is large and sparse the MINOS package (see Murtagh and Saunders [13]) should be used, since E04UCF treats all matrices as dense.

The user must supply an initial estimate of the solution to (1), together with subroutines that define F(x), c(x) and as many first partial derivatives as possible; unspecified derivatives are approximated by finite differences.

The objective function is defined by subroutine OBJFUN, and the nonlinear constraints are defined by subroutine CONFUN. On every call, these subroutines must return appropriate values of the objective and nonlinear constraints. The user should also provide the available partial derivatives. Any unspecified derivatives are approximated by finite differences; see Section 5.1 for a discussion of the optional parameter Derivative Level. Just before either OBJFUN or CONFUN is called, each element of the current gradient array OBJGRD or CJAC is initialised to a special value. On exit, any element that retains the value is estimated by finite differences. Note that if there are nonlinear costraints, then the first call to CONFUN will precede the first call to OBJFUN.

For maximum reliability, it is preferable for the user to provide all partial derivatives (see Chapter 8 of Gill et al [10], for a detailed discussion). If all gradients cannot be provided, it is similarly advisable to provide as many as possible. While developing the subroutines OBJFUN and CONFUN, the optional parameter Verify (see Section 5.1) should be used to check the calculation of any known gradients.

E04UCF implements a sequential quadratic programming (SQP) method. The document for E04NCF(*) should be consulted in conjunction with this document.

In the rest of this section we briefly summarize the main features of the method of E04UCF. Where possible, explicit reference is made to the names of variables that are parameters of subroutines E04UCF or appear in the printed output (see Section 5.2).

At a solution of (1), some of the constraints will be active, i.e., satisfied exactly. An active simple bound constraint implies that the corresponding variable is fixed at its bound, and hence the variables are partitioned into fixed and free variables. Let C denote the m by n matrix of gradients of the active general linear and nonlinear constraints. The number of fixed variables will be denoted by n_{FX}, with n_{FR} $(n_{FR}=n-n_{FX})$ the number of free variables. The subscripts 'FX' and 'FR' on a vector or matrix will denote the vector or matrix composed of the components corresponding to fixed or free variables.

A point x is a first-order Kuhn-Tucker point for (1) (see, e.g., Powell [14]) if the following conditions hold:

(i) x is feasible;

(ii) there exist vectors (xi) and (lambda) (the Lagrange multiplier vectors for the bound and general constraints) such that

$$g=C^T(\lambda)+(\xi), \qquad (2)$$

where g is the gradient of F evaluated at x, and $(\xi)_j=0$ if the jth variable is free.

(iii) The Lagrange multiplier corresponding to an inequality constraint active at its lower bound must be non-negative, and non-positive for an inequality constraint active at its upper bound.

Let Z denote a matrix whose columns form a basis for the set of vectors orthogonal to the rows of C_{FR}; i.e., $C_{FR}Z=0$. An equivalent statement of the condition (2) in terms of Z is

$$Z^Tg_{FR}=0.$$

The vector Z^Tg_{FR} is termed the projected gradient of F at x. Certain additional conditions must be satisfied in order for a first-order Kuhn-Tucker point to be a solution of (1) (see, e.g., Powell [14]).

The method of E04UCF is a sequential quadratic programming (SQP) method. For an overview of SQP methods, see, for example, Fletcher [5], Gill et al [10] and Powell [15].

The basic structure of E04UCF involves major and minor iterations. The major iterations generate a sequence of iterates $\{x_k\}$ that converge to x^*, a first-order Kuhn-Tucker point of (1).

At a typical major iteration, the new iterate $\bar{x}$ is defined by

$$\bar{x}=x+(\alpha)p \qquad (3)$$

where x is the current iterate, the non-negative scalar (alpha) is the step length, and p is the search direction. (For simplicity, we shall always consider a typical iteration and avoid reference to the index of the iteration.) Also associated with each major iteration are estimates of the Lagrange multipliers and a prediction of the active set.

The search direction p in (3) is the solution of a quadratic programming subproblem of the form

$$\text{Minimize } g^Tp+\frac{1}{2}p^THp, \quad \text{subject to } \bar{l}\le\begin{Bmatrix} p \\ A_Lp \end{Bmatrix}\le\bar{u}, \qquad (4)$$

```
      p              2                        { L }
                                              {A p}
                                              { N }
```

where g is the gradient of F at x, the matrix H is a positive-definite quasi-Newton approximation to the Hessian of the Lagrangian function (see Section 8.3), and A_N is the Jacobian matrix of c evaluated at x. (Finite-difference estimates may be used for g and A_N; see the optional parameter Derivative Level in Section 5.1.) Let l in (1) be partitioned into three sections: l_B, l_L and l_N, corresponding to the bound, linear and nonlinear constraints. The vector $\bar{l}$ in (4) is similarly partitioned, and is defined as

$$\bar{l}_B=l_B-x, \quad \bar{l}_L=l_L-A_L x, \quad \text{and } \bar{l}_N=l_N-c,$$

where c is the vector of nonlinear constraints evaluated at x.

The vector $\bar{u}$ is defined in an analogous fashion.

The estimated Lagrange multipliers at each major iteration are the Lagrange multipliers from the subproblem (4) (and similarly for the predicted active set). (The numbers of bounds, general linear and nonlinear constraints in the QP active set are the quantities Bnd, Lin and Nln in the printed output of E04UCF.) In E04UCF, (4) is solved using E04NCF(*). Since solving a quadratic program as an iterative procedure, the minor iterations of E04UCF are the iterations of E04NCF(*). (More details about solving the subproblem are given in Section 8.1.)

Certain matrices associated with the QP subproblem are relevant in the major iterations. Let the subscripts 'FX' and 'FR' refer to the predicted fixed and free variables, and let C denote the m by n matrix of gradients of the general linear and nonlinear constraints in the predicted active set. First, we have available the TQ factorization of C_{FR}:

$$C_{FR} Q_{FR} =(0 \; T), \qquad (5)$$

where T is a nonsingular m by m reverse-triangular matrix (i.e., $t_{ij}=0$ if i+j<m), and the non-singular n_{FR} by n_{FR} matrix Q_{FR} is

the product of orthogonal transformations (see Gill et al [6]).
Second, we have the upper-triangular Cholesky factor R of the
transformed and re-ordered Hessian matrix

$$R^T R=H_Q==Q^T\tilde{H}Q, \qquad (6)$$

where $\tilde{H}$ is the Hessian H with rows and columns permuted so that
the free variables are first, and Q is the n by n matrix

$$Q=\begin{pmatrix} Q_{FR} & \\ & I_{FX} \end{pmatrix}, \qquad (7)$$

with I_{FX} the identity matrix of order n_{FX}. If the columns of Q_{FR}
are partitioned so that

$$Q_{FR}=(Z\ Y),$$

the n_z ($n_z==n_{FR}-m$) columns of Z form a basis for the null space of
C_{FR}. The matrix Z is used to compute the projected gradient Z^Tg_{FR}
at the current iterate. (The values Nz, Norm Gf and Norm Gz
printed by E04UCF give n_z and the norms of g_{FR} and Z^Tg_{FR}.)

A theoretical characteristic of SQP methods is that the predicted
active set from the QP subproblem (4) is identical to the correct
active set in a neighbourhood of x^*. In E04UCF, this feature is
exploited by using the QP active set from the previous iteration
as a prediction of the active set for the next QP subproblem,
which leads in practice to optimality of the subproblems in only
one iteration as the solution is approached. Separate treatment
of bound and linear constraints in E04UCF also saves computation
in factorizing C_{FR} and H_Q.

Once p has been computed, the major iteration proceeds by
determining a step length (alpha) that produces a 'sufficient
decrease' in an augmented Lagrangian merit function (see Section
8.2). Finally, the approximation to the transformed Hessian

matrix H_Q is updated using a modified BFGS quasi-Newton update (see Section 8.3) to incorporate new curvature information obtained in the move from x to $\bar{x}$.

On entry to E04UCF, an iterative procedure from E04NCF(*) is executed, starting with the user-provided initial point, to find a point that is feasible with respect to the bounds and linear constraints (using the tolerance specified by Linear Feasibility Tolerance see Section 5.1). If no feasible point exists for the bound and linear constraints, (1) has no solution and E04UCF terminates. Otherwise, the problem functions will thereafter be evaluated only at points that are feasible with respect to the bounds and linear constraints. The only exception involves variables whose bounds differ by an amount comparable to the finite-difference interval (see the discussion of Difference Interval in Section 5.1). In contrast to the bounds and linear constraints, it must be emphasised that the nonlinear constraints will not generally be satisfied until an optimal point is reached.

Facilities are provided to check whether the user-provided gradients appear to be correct (see the optional parameter Verify in Section 5.1). In general, the check is provided at the first point that is feasible with respect to the linear constraints and bounds. However, the user may request that the check be performed at the initial point.

In summary, the method of E04UCF first determines a point that satisfies the bound and linear constraints. Thereafter, each iteration includes:

(a) the solution of a quadratic programming subproblem;

(b) a linesearch with an augmented Lagrangian merit function; and

(c) a quasi-Newton update of the approximate Hessian of the Lagrangian function.

These three procedures are described in more detail in Section 8.

5. Parameters

1: N -- INTEGER Input
On entry: the number, n, of variables in the problem.
Constraint: N > 0.

2: NCLIN -- INTEGER Input
On entry: the number, n_L, of general linear constraints in the problem. Constraint: NCLIN >= 0.

3: NCNLN -- INTEGER Input
On entry: the number, n_N, of nonlinear constraints in the problem. Constraint: NCNLN >= 0.

4: NROWA -- INTEGER Input
On entry:
the first dimension of the array A as declared in the (sub)program from which E04UCF is called.
Constraint: NROWA >= max(1,NCLIN).

5: NROWJ -- INTEGER Input
On entry:
the first dimension of the array CJAC as declared in the (sub)program from which E04UCF is called.
Constraint: NROWJ >= max(1,NCNLN).

6: NROWR -- INTEGER Input
On entry:
the first dimension of the array R as declared in the (sub)program from which E04UCF is called.
Constraint: NROWR >= N.

7: A(NROWA,*) -- DOUBLE PRECISION array Input
The second dimension of the array A must be >= N for NCLIN > 0. On entry: the ith row of the array A must contain the ith row of the matrix A_L of general linear constraints in (1). That is, the ith row contains the coefficients of the ith general linear constraint, for i = 1,2,...,NCLIN.

If NCLIN = 0 then the array A is not referenced.

8: BL(N+NCLIN+NCNLN) -- DOUBLE PRECISION array Input
On entry: the lower bounds for all the constraints, in the following order. The first n elements of BL must contain the lower bounds on the variables. If NCLIN > 0, the next n_L elements of BL must contain the lower bounds on the general linear constraints. If NCNLN > 0, the next n_N elements of BL must contain the lower bounds for the nonlinear constraints. To specify a non-existent lower bound (i.e., l_j =-infty), the value used must satisfy BL(j)<=-BIGBND, where BIGBND is the value of the optional parameter Infinite Bound Size whose default value is 10^{10} (see Section 5.1). To specify the jth constraint as an equality, the user must set BL(j) = BU(j) = (beta), say, where |(beta)|<BIGBND. Constraint: BL(j) <= BU(j), for j=1,2,...,N+NCLIN+NCNLN.

9: BU(N+NCLIN+NCNLN) -- DOUBLE PRECISION array Input
On entry: the upper bounds for all the constraints in the following order. The first n elements of BU must contain the upper bounds on the variables. If NCLIN > 0, the next n_L elements of BU must contain the upper bounds on the general linear constraints. If NCNLN > 0, the next n_N elements of BU must contain the upper bounds for the nonlinear constraints. To specify a non-existent upper bound (i.e., u_j =+infty), the value used must satisfy BU(j) >= BIGBND, where BIGBND is the value of the optional parameter Infinite Bound Size, whose default value is 10^{10} (see Section 5.1). To specify the jth constraint as an equality, the user must set BU(j) = BL(j) = (beta), say, where |(beta)| < BIGBND. Constraint: BU(j) >= BL(j), for j=1,2,...,N+NCLIN+NCNLN.

10: CONFUN -- SUBROUTINE, supplied by the user.
External Procedure
CONFUN must calculate the vector c(x) of nonlinear constraint functions and (optionally) its Jacobian for a specified n element vector x. If there are no nonlinear constraints (NCNLN=0), CONFUN will never be called by E04UCF and CONFUN may be the dummy routine E04UDM. (E04UDM is included in the NAG Foundation Library and so need not be supplied by the user. Its name may be implementation-dependent: see the Users' Note for your implementation for

details.) If there are nonlinear constraints, the first call to CONFUN will occur before the first call to OBJFUN.

Its specification is:

```
       SUBROUTINE CONFUN (MODE, NCNLN, N, NROWJ, NEEDC,
      1                   X, C, CJAC, NSTATE, IUSER,
      2                   USER)
       INTEGER          MODE, NCNLN, N, NROWJ, NEEDC
      1                 (NCNLN), NSTATE, IUSER(*)
       DOUBLE PRECISION X(N), C(NCNLN), CJAC(NROWJ,N),
      1                 USER(*)
```

1: MODE -- INTEGER Input/Output
On entry: MODE indicates the values that must be assigned during each call of CONFUN. MODE will always have the value 2 if all elements of the Jacobian are available, i.e., if Derivative Level is either 2 or 3 (see Section 5.1). If some elements of CJAC are unspecified, E04UCF will call CONFUN with MODE = 0, 1, or 2:

If MODE = 2, only the elements of C corresponding to positive values of NEEDC must be set (and similarly for the available components of the rows of CJAC).

If MODE = 1, the available components of the rows of CJAC corresponding to positive values in NEEDC must be set. Other rows of CJAC and the array C will be ignored.

If MODE = 0, the components of C corresponding to positive values in NEEDC must be set. Other components and the array CJAC are ignored. On exit: MODE may be set to a negative value if the user wishes to terminate the solution to the current problem. If MODE is negative on exit from CONFUN then E04UCF will terminate with IFAIL set to MODE.

2: NCNLN -- INTEGER Input
On entry: the number, n_N, of nonlinear constraints.

3: N -- INTEGER Input
On entry: the number, n, of variables.

4: NROWJ -- INTEGER Input
On entry: the first dimension of the array CJAC.

5: NEEDC(NCNLN) -- INTEGER array Input

```
    On entry: the indices of the elements of C or CJAC that
    must be evaluated by CONFUN. If NEEDC(i)>0 then the ith
    element of C and/or the ith row of CJAC (see parameter
    MODE above) must be evaluated at x.

6:  X(N) -- DOUBLE PRECISION array                    Input
    On entry: the vector x of variables at which the
    constraint functions are to be evaluated.

7:  C(NCNLN) -- DOUBLE PRECISION array               Output
    On exit: if NEEDC(i)>0 and MODE = 0 or 2, C(i) must
    contain the value of the ith constraint at x. The
    remaining components of C, corresponding to the non-
    positive elements of NEEDC, are ignored.

8:  CJAC(NROWJ,N) -- DOUBLE PRECISION array          Output
    On exit: if NEEDC(i)>0 and MODE = 1 or 2, the ith row
    of CJAC must contain the available components of the
    vector (nabla)c  given by
                   i
                         ( ddc   ddc       ddc )
                         (    i     i         i)T
              (nabla)c =( ----, ----,..., ----) ,
                      i ( ddx   ddx       ddx )
                         (    1     2         n)
           ddc
              i
    where  ---- is the partial derivative of the ith
           ddx
              j
    constraint with respect to the jth variable, evaluated
    at the point x. See also the parameter NSTATE below.
    The remaining rows of CJAC, corresponding to non-
    positive elements of NEEDC, are ignored.

    If all constraint gradients (Jacobian elements) are
    known (i.e., Derivative Level = 2 or 3; see Section 5.1)
    any constant elements may be assigned to CJAC one
    time only at the start of the optimization. An element
    of CJAC that is not subsequently assigned in CONFUN
    will retain its initial value throughout. Constant
    elements may be loaded into CJAC either before the call
    to E04UCF or during the first call to CONFUN (signalled
    by the value NSTATE = 1). The ability to preload
    constants is useful when many Jacobian elements are
    identically zero, in which case CJAC may be initialised
    to zero and non-zero elements may be reset by CONFUN.

    Note that constant non-zero elements do affect the
    values of the constraints. Thus, if CJAC(i,j) is set to
```

```
          a constant value, it need not be reset in subsequent
          calls to CONFUN, but the value CJAC(i,j)*X(j) must
          nonetheless be added to C(i).

          It must be emphasized that, if Derivative Level < 2,
          unassigned elements of CJAC are not treated as
          constant; they are estimated by finite differences, at
          non-trivial expense. If the user does not supply a
          value for Difference Interval (see Section 5.1), an
          interval for each component of x is computed
          automatically at the start of the optimization. The
          automatic procedure can usually identify constant
          elements of CJAC, which are then computed once only by
          finite differences.

      9:  NSTATE -- INTEGER                                   Input
          On entry: if NSTATE = 1 then E04UCF is calling CONFUN
          for the first time. This parameter setting allows the
          user to save computation time if certain data must be
          read or calculated only once.

     10:  IUSER(*) -- INTEGER array                User Workspace

     11:  USER(*) -- DOUBLE PRECISION array        User Workspace
          CONFUN is called from E04UCF with the parameters IUSER
          and USER as supplied to E04UCF. The user is free to use
          the arrays IUSER and USER to supply information to
          CONFUN as an alternative to using COMMON.
     CONFUN must be declared as EXTERNAL in the (sub)program
     from which E04UCF is called. Parameters denoted as
     Input must not be changed by this procedure.

 11:  OBJFUN -- SUBROUTINE, supplied by the user.
                                                 External Procedure
     OBJFUN must calculate the objective function F(x) and
     (optionally) the gradient g(x) for a specified n element
     vector x.

     Its specification is:

            SUBROUTINE OBJFUN (MODE, N, X, OBJF, OBJGRD,
           1                   NSTATE, IUSER, USER)
            INTEGER          MODE, N, NSTATE, IUSER(*)
            DOUBLE PRECISION X(N), OBJF, OBJGRD(N), USER(*)

      1:  MODE -- INTEGER                              Input/Output
          On entry: MODE indicates the values that must be
          assigned during each call of OBJFUN.

          MODE will always have the value 2 if all components of
          the objective gradient are specified by the user, i.e.,
          if Derivative Level is either 1 or 3. If some gradient
          elements are unspecified, E04UCF will call OBJFUN with
          MODE = 0, 1 or 2.
               If MODE = 2, compute OBJF and the available
               components of OBJGRD.

               If MODE = 1, compute all available components of
               OBJGRD; OBJF is not required.

               If MODE = 0, only OBJF needs to be computed;
               OBJGRD is ignored.
          On exit: MODE may be set to a negative value if the
          user wishes to terminate the solution to the current
          problem. If MODE is negative on exit from OBJFUN, then
          E04UCF will terminate with IFAIL set to MODE.

      2:  N -- INTEGER                                    Input
          On entry: the number, n, of variables.

      3:  X(N) -- DOUBLE PRECISION array                  Input
          On entry: the vector x of variables at which the
          objective function is to be evaluated.

      4:  OBJF -- DOUBLE PRECISION                       Output
          On exit: if MODE = 0 or 2, OBJF must be set to the
          value of the objective function at x.

      5:  OBJGRD(N) -- DOUBLE PRECISION array            Output
          On exit: if MODE = 1 or 2, OBJGRD must return the
          available components of the gradient evaluated at x.

      6:  NSTATE -- INTEGER                               Input
          On entry: if NSTATE = 1 then E04UCF is calling OBJFUN
          for the first time. This parameter setting allows the
          user to save computation time if certain data must be
          read or calculated only once.

      7:  IUSER(*) -- INTEGER array              User Workspace

      8:  USER(*) -- DOUBLE PRECISION array      User Workspace
          OBJFUN is called from E04UCF with the parameters IUSER
          and USER as supplied to E04UCF. The user is free to use
          the arrays IUSER and USER to supply information to
          OBJFUN as an alternative to using COMMON.
     OBJFUN must be declared as EXTERNAL in the (sub)program
     from which E04UCF is called. Parameters denoted as
     Input must not be changed by this procedure.

 12:  ITER -- INTEGER                                    Output
```

On exit: the number of iterations performed.

13: ISTATE(N+NCLIN+NCNLN) -- INTEGER array Input/Output
On entry: ISTATE need not be initialised if E04UCF is called with (the default) Cold Start option. The ordering of ISTATE is as follows. The first n elements of ISTATE refer to the upper and lower bounds on the variables, elements n+1 through $n+n_L$ refer to the upper and lower bounds on $A_L x$, and elements $n+n_L+1$ through $n+n_L+n_N$ refer to the upper and lower bounds on c(x). When a Warm Start option is chosen, the elements of ISTATE corresponding to the bounds and linear constraints define the initial working set for the procedure that finds a feasible point for the linear constraints and bounds. The active set at the conclusion of this procedure and the elements of ISTATE corresponding to nonlinear constraints then define the initial working set for the first QP subproblem. Possible values for ISTATE(j) are:

ISTATE(j)	Meaning
0	The corresponding constraint is not in the initial QP working set.
1	This inequality constraint should be in the working set at its lower bound.
2	This inequality constraint should be in the working set at its upper bound.
3	This equality constraint should be in the initial working set. This value must not be specified unless BL(j) = BU(j). The values 1,2 or 3 all have the same effect when BL(j) = BU(j).

Note that if E04UCF has been called previously with the same values of N, NCLIN and NCNLN, ISTATE already contains satisfactory values. If necessary, E04UCF will override the user's specification of ISTATE so that a poor choice will not cause the algorithm to fail. On exit: with IFAIL = 0 or 1, the values in the array ISTATE correspond to the active set of the final QP subproblem, and are a prediction of the status of the constraints at the solution of the problem. Otherwise, ISTATE indicates the composition of the QP working set at the final iterate. The significance of each possible value of ISTATE(j) is as follows:

-2	This constraint violates its lower bound by more than the appropriate feasibility tolerance (see the optional parameters LinearFeasibility Tolerance and Nonlinear Feasibility Tolerance in

```
                 Section 5.1). This value can occur only when no
                 feasible point can be found for a QP subproblem.

          -1     This constraint violates its upper bound by more
                 than the appropriate feasibility tolerance (see
                 the optional parameters Linearear Feasibility
                 Tolerance and Nonlinear Feasibility Tolerance in
                 Section 5.1). This value can occur only when no
                 feasible point can be found for a QP subproblem.

          0      The constraint is satisfied to within the
                 feasibility tolerance, but is not in the working
                 set.

          1      This inequality constraint is included in the QP
                 working set at its upper bound.

          2      This inequality constraint is included in the QP
                 working set at its upper bound.

          3      This constraint is included in the QP working set
                 as an equality. This value of ISTATE can occur
                 only when BL(j) = BU(j).

     14:  C(*) -- DOUBLE PRECISION array                        Output
          Note: the dimension of the array C must be at least
          max(1,NCNLN).
          On exit: if NCNLN > 0, C(i) contains the value of the ith
          nonlinear constraint function c  at the final iterate, for
                                         i
          i=1,2,...,NCNLN. If NCNLN = 0, then the array C is not
          referenced.

     15:  CJAC(NROWJ,*) -- DOUBLE PRECISION array         Input/Output
          Note: the second dimension of the array CJAC must be at
          least N for NCNLN >0 and 1 otherwise On entry: in general,
          CJAC need not be initialised before the call to E04UCF.
          However, if Derivative Level = 3, the user may optionally
          set the constant elements of CJAC (see parameter NSTATE in
          the description of CONFUN). Such constant elements need not
          be re-assigned on subsequent calls to CONFUN. If NCNLN = 0,
          then the array CJAC is not referenced. On exit: if NCNLN >
          0, CJAC contains the Jacobian matrix of the nonlinear
          constraint functions at the final iterate, i.e., CJAC(i,j)
          contains the partial derivative of the ith constraint
          function with respect to the jth variable, for i=1,2,...,
          NCNLN; j = 1,2,...,N. (See the discussion of parameter CJAC
          under CONFUN.)

     16:  CLAMDA(N+NCLIN+NCNLN) -- DOUBLE PRECISION array Input/Output
```

On entry: CLAMDA need not be initialised if E04UCF is called with the (default) Cold Start option. With the Warm Start option, CLAMDA must contain a multiplier estimate for each nonlinear constraint with a sign that matches the status of the constraint specified by the ISTATE array (as above). The ordering of CLAMDA is as follows; the first n elements contain the multipliers for the bound constraints on the variables, elements n+1 through $n+n_L$ contain the multipliers for the general linear constraints, and elements $n+n_L+1$ through $n+n_L+n_N$ contain the multipliers for the nonlinear constraints. If the jth constraint is defined as 'inactive' by the initial value of the ISTATE array, CLAMDA(j) should be zero; if the jth constraint is an inequality active at its lower bound, CLAMDA(j) should be non-negative; if the j th constraint is an inequality active at its upper bound, CLAMDA(j) should be non-positive. On exit: the values of the QP multipliers from the last QP subproblem. CLAMDA(j) should be non-negative if ISTATE(j) = 1 and non-positive if ISTATE(j) = 2.

17: OBJF -- DOUBLE PRECISION Output
On exit: the value of the objective function, F(x), at the final iterate.

18: OBJGRD(N) -- DOUBLE PRECISION array Output
On exit: the gradient (or its finite-difference approximation) of the objective function at the final iterate.

19: R(NROWR,N) -- DOUBLE PRECISION array Input/Output
On entry: R need not be initialised if E04UCF is called with a Cold Start option (the default), and will be taken as the identity. With a Warm Start R must contain the upper-triangular Cholesky factor R of the initial approximation of the Hessian of the Lagrangian function, with the variables in the natural order. Elements not in the upper-triangular part of R are assumed to be zero and need not be assigned. On exit: if Hessian = No, (the default; see Section 5.1), R contains the upper-triangular Cholesky factor R of $Q^T\tilde{H}Q$, an estimate of the transformed and re-ordered Hessian of the Lagrangian at x (see (6) in Section 3). If Hessian = Yes, R contains the upper-triangular Cholesky factor R of H, the approximate (untransformed) Hessian of the Lagrangian, with the variables in the natural order.

20: X(N) -- DOUBLE PRECISION array Input/Output

```
     On entry: an initial estimate of the solution. On exit: the
     final estimate of the solution.

21:  IWORK(LIWORK) -- INTEGER array                    Workspace

22:  LIWORK -- INTEGER                                     Input
     On entry:
     the dimension of the array IWORK as declared in the
     (sub)program from which E04UCF is called.
     Constraint: LIWORK>=3*N+NCLIN+2*NCNLN.

23:  WORK(LWORK) -- DOUBLE PRECISION array             Workspace

24:  LWORK -- INTEGER                                      Input
     On entry:
     the dimension of the array WORK as declared in the
     (sub)program from which E04UCF is called.
     Constraints:
     if NCLIN = NCNLN = 0 then
           LWORK >=20*N

     if NCNLN = 0 and NCLIN > 0 then
                     2
           LWORK >=2*N +20*N+11*NCLIN

     if NCNLN > 0 and NCLIN >= 0 then
                    2
           LWORK>=2*N +N*NCLIN+20*N*NCNLN+20*N+ 11*NCLIN+21*NCNLN

     If Major Print Level > 0, the required amounts of workspace
     are output on the current advisory message channel (see
     X04ABF). As an alternative to computing LIWORK and LWORK
     from the formulas given above, the user may prefer to obtain
     appropriate values from the output of a preliminary run with
     a positive value of Major Print Level and LIWORK and LWORK
     set to 1. (E04UCF will then terminate with IFAIL = 9.)

25:  IUSER(*) -- INTEGER array                    User Workspace
     Note: the dimension of the array IUSER must be at least 1.
     IUSER is not used by E04UCF, but is passed directly to
     routines CONFUN and OBJFUN and may be used to pass
     information to those routines.

26:  USER(*) -- DOUBLE PRECISION array            User Workspace
     Note: the dimension of the array USER must be at least 1.
     USER is not used by E04UCF, but is passed directly to
     routines CONFUN and OBJFUN and may be used to pass
     information to those routines.

27:  IFAIL -- INTEGER                               Input/Output
```

On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL /=0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

E04UCF returns with IFAIL = 0 if the iterates have converged to a point x that satisfies the first-order Kuhn-Tucker conditions to the accuracy requested by the optional parameter Optimality Tolerance (see Section 5.1), i.e., the projected gradient and active constraint residuals are negligible at x.

The user should check whether the following four conditions are satisfied:

(i) the final value of Norm Gz is significantly less than that at the starting point;

(ii) during the final major iterations, the values of Step and ItQP are both one;

(iii) the last few values of both Norm Gz and Norm C become small at a fast linear rate;

(iv) Cond Hz is small.

If all these conditions hold, x is almost certainly a local minimum of (1). (See Section 9 for a specific example.)

5.1. Optional Input Parameters

Several optional parameters in E04UCF define choices in the behaviour of the routine. In order to reduce the number of formal parameters of E04UCF these optional parameters have associated default values (see Section 5.1.3) that are appropriate for most problems. Therefore the user need only specify those optional parameters whose values are to be different from their default values.

The remainder of this section can be skipped by users who wish to use the default values for all optional prameters. A complete list of optional parameters and their default values is given in Section 5.1.3

5.1.1. Specification of the optional parameters

Optional parameters may be specified by calling one, or both, of
E04UDF and E04UEF prior to a call to E04UCF.

E04UDF reads options from an external options file, with Begin
and End as the first and last lines respectively and each
intermediate line defining a single optional parameter. For
example,

```
      Begin
        Print Level = 1
      End
```

The call

```
      CALL E04UDF (IOPTNS, INFORM)
```

can then be used to read the file on unit IOPTNS. INFORM will be
zero on successful exit. E04UDF should be consulted for a full
description of this method of supplying optional parameters.

E04UEF can be called directly to supply options, one call being
necessary for each optional parameter. For example,

```
      CALL E04UEF ('Print level = 1')
```

E04UEF should be consulted for a full description of this method
of supplying optional parameters.

All optional parameters not specified by the user are set to
their default values. Optional parameters specified by the user
are unaltered by E04UCF (unless they define invalid values) and
so remain in effect for subsequent calls to E04UCF, unless
altered by the user.

5.1.2. Description of the optional parameters

The following list (in alphabetical order) gives the valid
options. For each option, we give the keyword, any essential
optional qualifiers, the default value, and the definition. The
minimum valid abbreviation of each keyword is underlined. If no
characters of an optional qualifier are underlined, the qualifier
may be omitted. The letter a denotes a phrase (character string)
that qualifies an option. The letters i and r denote INTEGER and
DOUBLE PRECISION values required with certain options. The number
(epsilon) is a generic notation for machine precision (see
X02AJF(*)), and $(epsilon)_R$ denotes the relative precision of the
objective function (the optional parameter Function Precision see
below).

Central Difference Interval r Default values are computed

If the algorithm switches to central differences because the
forward-difference approximation is not sufficiently accurate,
the value of r is used as the difference interval for every
component of x. The use of finite-differences is discussed
further below under the optional parameter Difference Interval.

Cold Start Default = Cold Start

Warm Start

(Axiom parameter STA, warm start when .TRUE.)

This option controls the specification of the initial working set
in both the procedure for finding a feasible point for the linear
constraints and bounds, and in the first QP subproblem
thereafter. With a Cold Start, the first working set is chosen by
E04UCF based on the values of the variables and constraints at
the initial point. Broadly speaking, the initial working set will
include equality constraints and bounds or inequality constraints
that violate or 'nearly' satisfy their bounds (within Crash
Tolerance; see below). With a Warm Start, the user must set the
ISTATE array and define CLAMDA and R as discussed in Section 5.
ISTATE values associated with bounds and linear constraints
determine the initial working set of the procedure to find a
feasible point with respect to the bounds and linear constraints.
ISTATE values associated with nonlinear constraints determine the
initial working set of the first QP subproblem after such a
feasible point has been found. E04UCF will override the user's
specification of ISTATE if necessary, so that a poor choice of
the working set will not cause a fatal error. A warm start will
be advantageous if a good estimate of the initial working set is
available - for example, when E04UCF is called repeatedly to
solve related problems.

Crash Tolerance r Default = 0.01

(Axiom parameter CRA)

This value is used in conjunction with the optional parameter
Cold Start (the default value). When making a cold start, the QP
algorithm in E04UCF must select an initial working set. When r>=0
, the initial working set will include (if possible) bounds or
general inequality constraints that lie within r of their bounds.
In particular, a constraint of the form $a_j^T x>=l$ will be included

T

in the initial working set if $|a_j x-l|<=r(1+|l|)$. If r<0 or r>1, the default value is used.

Defaults

This special keyword may be used to reset the default values following a call to E04UCF.

Derivative Level i Default = 3

(Axiom parameter DER)

This parameter indicates which derivatives are provided by the user in subroutines OBJFUN and CONFUN. The possible choices for i are the following.

i	Meaning
3	All objective and constraint gradients are provided by the user.
2	All of the Jacobian is provided, but some components of the objective gradient are not specified by the user.
1	All elements of the objective gradient are known, but some elements of the Jacobian matrix are not specified by the user.
0	Some elements of both the objective gradient and the Jacobian matrix are not specified by the user.

The value i=3 should be used whenever possible, since E04UCF is more reliable and will usually be more efficient when all derivatives are exact.

If i=0 or 2, E04UCF will estimate the unspecified components of the objective gradient, using finite differences. The computation of finite-difference approximations usually increases the total run-time, since a call to OBJFUN is required for each unspecified element. Furthermore, less accuracy can be attained in the solution (see Chapter 8 of Gill et al [10], for a discussion of limiting accuracy).

If i=0 or 1, E04UCF will approximate unspecified elements of the Jacobian. One call to CONFUN is needed for each variable for which partial derivatives are not available. For example, if the Jacobian has the form

(* * * *)

```
                         (* ? ? *)
                         (* * ? *)
                         (* * * *)

where '*' indicates an element provided by the user and '?'
indicates an unspecified element, E04UCF will call CONFUN twice:
once to estimate the missing element in column 2, and again to
estimate the two missing elements in column 3. (Since columns 1
and 4 are known, they require no calls to CONFUN.)

At times, central differences are used rather than forward
differences, in which case twice as many calls to OBJFUN and
CONFUN are needed. (The switch to central differences is not
under the user's control.)

Difference Interval r Default values are computed

   (Axiom parameter DIF)

This option defines an interval used to estimate gradients by
finite differences in the following circumstances:

(a)   For verifying the objective and/or constraint gradients
      (see the description of Verify, below).

(b)   For estimating unspecified elements of the objective
      gradient of the Jacobian matrix.

In general, a derivative with respect to the jth variable is
                                                             ^
approximated using the interval (delta) , where (delta) =r(1+|x |)
                                       j               j      j
        ^

with x the first point feasible with respect to the bounds and
linear constraints. If the functions are well scaled, the
resulting derivative approximation should be accurate to O(r).

See Gill et al [10] for a discussion of the accuracy in finite-
difference approximations.

If a difference interval is not specified by the user, a finite-
difference interval will be computed automatically for each
variable by a procedure that requires up to six calls of CONFUN
and OBJFUN for each component. This option is recommended if the
function is badly scaled or the user wishes to have E04UCF
determine constant elements in the objective and constraint
gradients (see the descriptions of CONFUN and OBJFUN in
Section 5).
```

```
Feasibility Tolerance r Default = \/(epsilon)

   (Axiom parameter FEA)

The scalar r defines the maximum acceptable absolute violations
in linear and nonlinear constraints at a 'feasible' point; i.e.,
a constraint is considered satisfied if its violation does not
exceed r. If r<(epsilon) or r>=1, the default value is used.
Using this keyword sets both optional parameters Linear
Feasibility Tolerance and Nonlinear Feasibility Tolerance to r,
if (epsilon)<=r<1. (Additional details are given below under the
descriptions of these parameters.)

                                        0.9
Function Precision r Default = (epsilon)

   (Axiom parameter FUN)

This parameter defines (epsilon) , which is intended to be a
                                R
measure of the accuracy with which the problem functions f and c
can be computed. If r<(epsilon) or r>=1, the default value is
used. The value of (epsilon)  should reflect the relative
                            R
precision of 1+|F(x)|; i.e., (epsilon)  acts as a relative
                                      R
precision when |F| is large, and as an absolute precision when
|F| is small. For example, if F(x) is typically of order 1000 and
the first six significant digits are known to be correct, an
appropriate value for (epsilon)  would be 1.0E-6. In contrast, if
                               R
                             -4
F(x) is typically of order 10   and the first six significant
digits are known to be correct, an appropriate value for
(epsilon)  would be 1.0E-10. The choice of (epsilon)  can be
         R                                         R
quite complicated for badly scaled problems; see Chapter 8 of
Gill et al [10] for a discussion of scaling techniques. The
default value is appropriate for most simple functions that are
computed with full accuracy. However, when the accuracy of the
computed function values is known to be significantly worse than
full precision, the value of (epsilon)  should be large enough so
                                      R
that E04UCF will not attempt to distinguish between function
values that differ by less than the error inherent in the
calculation.

Hessian No Default = No

Hessian Yes
```

(No Axiom parameter - fixed as Yes)

This option controls the contents of the upper-triangular matrix R (see Section 5). E04UCF works exclusively with the transformed and re-ordered Hessian H_Q (6), and hence extra computation is required to form the Hessian itself. If Hessian = No, R contains the Cholesky factor of the transformed and re-ordered Hessian. If Hessian = Yes the Cholesky factor of the approximate Hessian itself is formed and stored in R. The user should select Hessian = Yes if a warm start will be used for the next call to E04UCF.

Infinite Bound Size r Default = 10^{10}

(Axiom parameter INFB)

If r>0, r defines the 'infinite' bound BIGBND in the definition of the problem constraints. Any upper bound greater than or equal to BIGBND will be regarded as plus infinity (and similarly for a lower bound less than or equal to -BIGBND). If r<=0, the default value is used.

Infinite Step Size r Default = max(BIGBND,10^{10})

(Axiom parameter INFS)

If r>0, r specifies the magnitude of the change in variables that is treated as a step to an unbounded solution. If the change in x during an iteration would exceed the value of Infinite Step Size, the objective function is considered to be unbounded below in the feasible region. If r<=0, the default value is used.

Iteration limit i Default = max(50,3($n+n_L$)+10n_N)

See Major Iteration Limit below.

Linear Feasibility Tolerance r_1 Default = $\sqrt{\epsilon}$

(Axiom parameter LINF)

Nonlinear Feasibility Tolerance r_2 Default = $\sqrt{\epsilon}$ if

```
   (Axiom parameter NONF)
                                    0.33
Derivative Level >= 2 and (epsilon)     otherwise

The scalars r  and r  define the maximum acceptable absolute
             1      2
violations in linear and nonlinear constraints at a 'feasible'
point; i.e., a linear constraint is considered satisfied if its
violation does not exceed r , and similarly for a nonlinear
                           1
constraint and r . If r <(epsilon) or r >=1, the default value is
                2      i               i
used, for i=1,2.

On entry to E04UCF, an iterative procedure is executed in order
to find a point that satisfies the linear constraint and bounds
on the variables to within the tolerance r . All subsequent
                                          1
iterates will satisfy the linear constraints to within the same
tolerance (unless r  is comparable to the finite-difference
                   1
interval).

For nonlinear constraints, the feasibility tolerance r  defines
                                                      2
the largest constraint violation that is acceptable at an optimal
point. Since nonlinear constraints are generally not satisfied
until the final iterate, the value of Nonlinear Feasibility
Tolerance acts as a partial termination criterion for the
iterative sequence generated by E04UCF (see the discussion of
Optimality Tolerance).

These tolerances should reflect the precision of the
corresponding constraints. For example, if the variables and the
coefficients in the linear constraints are of order unity, and
the latter are correct to about 6 decimal digits, it would be
                              - 6
appropriate to specify r  as 10   .
                        1

Linesearch Tolerance r Default = 0.9

   (Axiom parameter LINT)

The value r (0 <= r < 1) controls the accuracy with which the
step (alpha) taken during each iteration approximates a minimum
of the merit function along the search direction (the smaller the
value of r, the more accurate the linesearch). The default value
r=0.9 requests an inaccurate search, and is appropriate for most
```

problems, particularly those with any nonlinear constraints.

If there are no nonlinear constraints, a more accurate search may be appropriate when it is desirable to reduce the number of major iterations - for example, if the objective function is cheap to evaluate, or if a substantial number of gradients are unspecified.

List Default = List

Nolist

(Axiom parameter LIST)

Normally each optional parameter specification is printed as it is supplied. Nolist may be used to suppress the printing and List may be used to restore printing.

Major Iteration Limit i Default = $\max(50,3(n+n_L)+10n_N)$

Iteration Limit

Iters

Itns

(Axiom parameter MAJI)

The value of i specifies the maximum number of major iterations allowed before termination. Setting i=0 and Major Print Level> 0 means that the workspace needed will be computed and printed, but no iterations will be performed.

Major Print level i Default = 10

Print Level

(Axiom parameter MAJP)

The value of i controls the amount of printout produced by the major iterations of E04UCF. (See also Minor Print level below.) The levels of printing are indicated below.

i	Output
0	No output.
1	The final solution only.

5	One line for each major iteration (no printout of the final solution).
>=10	The final solution and one line of output for each iteration.
>=20	At each major iteration, the objective function, the Euclidean norm of the nonlinear constraint violations, the values of the nonlinear constraints (the vector c), the values of the linear constraints (the vector $A_L x$), and the current values of the variables (the vector x).
>=30	At each major iteration, the diagonal elements of the matrix T associated with the TQ factorization (5) of the QP working set, and the diagonal elements of R, the triangular factor of the transformed and re-ordered Hessian (6).

Minor Iteration Limit i Default = $\max(50,3(n+n_L+n_N))$

(Axiom parameter MINI)

The value of i specifies the maximum number of iterations for the optimality phase of each QP subproblem.

Minor Print Level i Default = 0

(Axiom parameter MINP)

The value of i controls the amount of printout produced by the minor iterations of E04UCF, i.e., the iterations of the quadratic programming algorithm. (See also Major Print Level, above.) The following levels of printing are available.

i	Output
0	No output.
1	The final QP solution.
5	One line of output for each minor iteration (no printout of the final QP solution).
>=10	The final QP solution and one brief line of output for each minor iteration.
>=20	At each minor iteration, the current estimates of the QP multipliers, the current estimate of the QP search

direction, the QP constraint values, and the status of each QP constraint.

≥ 30 At each minor iteration, the diagonal elements of the matrix T associated with the TQ factorization (5) of the QP working set, and the diagonal elements of the Cholesky factor R of the transformed Hessian (6).

Nonlinear Feasibility Tolerance r Default = $\sqrt{\epsilon}$

See Linear Feasibility Tolerance, above.

Optimality Tolerance r Default = $\epsilon^{0.8}$

(Axiom parameter OPT)

The parameter r ($\epsilon_R \le r < 1$) specifies the accuracy to which the user wishes the final iterate to approximate a solution of the problem. Broadly speaking, r indicates the number of correct figures desired in the objective function at the solution. For example, if r is 10^{-6} and E04UCF terminates successfully, the final value of F should have approximately six correct figures. If $r < \epsilon_R$ or $r \ge 1$ the default value is used.

E04UCF will terminate successfully if the iterative sequence of x -values is judged to have converged and the final point satisfies the first-order Kuhn-Tucker conditions (see Section 3). The sequence of iterates is considered to have converged at x if

$$\alpha \|p\| \le \sqrt{r}(1+\|x\|), \tag{8a}$$

where p is the search direction and α the step length from (3). An iterate is considered to satisfy the first-order conditions for a minimum if

$$\|Z^T g_{FR}\| \le \sqrt{r}(1+\max(1+|F(x)|,\|g_{FR}\|)) \tag{8b}$$

and

$$|res_j| \le ftol \text{ for all } j, \tag{8c}$$

where $Z^T g_{FR}$ is the projected gradient (see Section 3), g_{FR} is the gradient of F(x) with respect to the free variables, res_j is the violation of the jth active nonlinear constraint, and ftol is the Nonlinear Feasibility Tolerance.

Step Limit r Default = 2.0

(Axiom parameter STE)

If r>0, r specifies the maximum change in variables at the first step of the linesearch. In some cases, such as $F(x)=ae^{bx}$ or $F(x)=ax^b$, even a moderate change in the components of x can lead to floating-point overflow. The parameter r is therefore used to encourage evaluation of the problem functions at meaningful points. Given any major iterate x, the first point $\tilde{x}$ at which F and c are evaluated during the linesearch is restricted so that

$$||\tilde{x}-x||_2 <=r(1+||x||_2).$$

The linesearch may go on and evaluate F and c at points further from x if this will result in a lower value of the merit function. In this case, the character L is printed at the end of the optional line of printed output, (see Section 5.2). If L is printed for most of the iterations, r should be set to a larger value.

Wherever possible, upper and lower bounds on x should be used to prevent evaluation of nonlinear functions at wild values. The default value Step Limit = 2.0 should not affect progress on well-behaved functions, but values 0.1 or 0.01 may be helpful when rapidly varying functions are present. If a small value of Step Limit is selected, a good starting point may be required. An important application is to the class of nonlinear least-squares problems. If r<=0, the default value is used.

Start Objective Check At Variable k Default = 1

(Axiom parameter STAO)

Start Constraint Check At Variable k Default = 1

(Axiom parameter STAC)

```
Stop Objective Check At Variable l Default = n

   (Axiom parameter STOO)

Stop Constraint Check At Variable l Default = n

   (Axiom parameter STOC)

These keywords take effect only if Verify Level > 0 (see below).
They may be used to control the verification of gradient elements
computed by subroutines OBJFUN and CONFUN. For example, if the
first 30 components of the objective gradient appeared to be
correct in an earlier run, so that only component 31 remains
questionable, it is reasonable to specify Start Objective Check
At Variable 31. If the first 30 variables appear linearly in the
objective, so that the corresponding gradient elements are
constant, the above choice would also be appropriate.

Verify Level i Default = 0

Verify No

Verify Level - 1

Verify Level 0

Verify Objective Gradients

Verify Level 1

Verify Constraint Gradients

Verify Level 2

Verify

Verify Yes

Verify Gradients

Verify Level 3

   (Axiom parameter VE)

These keywords refer to finite-difference checks on the gradient
elements computed by the user-provided subroutines OBJFUN and
CONFUN. (Unspecified gradient components are not checked.) It is
possible to specify Verify Levels 0-3 in several ways, as
indicated above. For example, the nonlinear objective gradient
```

```
(if any) will be verified if either Verify Objective Gradients or
Verify Level 1 is specified. Similarly, the objective and the
constraint gradients will be verified if Verify Yes or Verify
Level 3 or Verify is specified.

If 0<=i<=3, gradients will be verified at the first point that
satisfies the linear constraints and bounds. If i=0, only a '
cheap' test will be performed, requiring one call to OBJFUN and
one call to CONFUN. If 1<=i<=3, a more reliable (but more
expensive) check will be made on individual gradient components,
within the ranges specified by the Start and Stop keywords
described above. A result of the form OK or BAD? is printed by
E04UCF to indicate whether or not each component appears to be
correct.

If 10<=i<=13, the action is the same as for i - 10, except that
it will take place at the user-specified initial value of x.

We suggest that Verify Level 3 be specified whenever a new
function routine is being developed.

5.1.3. Optional parameter checklist and default values

For easy reference, the following list shows all the valid
keywords and their default values. The symbol (epsilon)
represents the machine precision (see X02AJF(*) ).

Optional Parameters      Default Values

Central difference       Computed automatically
interval

Cold/Warm start          Cold start

Crash tolerance          0.01

Defaults

Derivative level         3

Difference interval      Computed automatically

                           ---------
Feasibility tolerance    \/(epsilon)

                                   0.9
Function precision       (epsilon)
```

Hessian	No
Infinite bound size	10^{10}
Infinite step size	10^{10}
Linear feasibility tolerance	$\sqrt{(\epsilon)}$
Linesearch tolerance	0.9
List/Nolist	List
Major iteration limit	$\max(50,3(n+n_L)+10n_N)$
Major print level	10
Minor iteration limit	$\max(50,3(n+n_L+n_N))$
Minor print level	0
Nonlinear feasibility tolerance	$\sqrt{(\epsilon)}$ if Derivative Level >= 2 otherwise $(\epsilon)^{0.33}$
Optimality tolerance	$(\epsilon)_R^{0.8}$
Step limit	2.0
Start objective check	1
Start constraint check	1
Stop objective check	n
Stop constraint check	n
Verify level	0

5.2. Description of Printed Output

The level of printed output from E04UCF is controlled by the user (see the description of Major Print Level and Minor Print Level in Section 5.1). If Minor Print Level > 0, output is obtained from the subroutines that solve the QP subproblem. For a detailed description of this information the reader should refer to E04NCF(*).

When Major Print Level >= 5, the following line of output is produced at every major iteration of E04UCF. In all cases, the values of the quantities printed are those in effect on completion of the given iteration.

Itn	is the iteration count.
ItQP	is the sum of the iterations required by the feasibility and optimality phases of the QP subproblem. Generally, ItQP will be 1 in the later iterations, since theoretical analysis predicts that the correct active set will be identified near the solution (see Section 3).
	Note that ItQP may be greater than the Minor Iteration Limit if some iterations are required for the feasibility phase.
Step	is the step (alpha) taken along the computed search direction. On reasonably well-behaved problems, the unit step will be taken as the solution is approached.
Nfun	is the cumulative number of evaluations of the objective function needed for the linesearch. Evaluations needed for the estimation of the gradients by finite differences are not included. Nfun is printed as a guide to the amount of work required for the linesearch.
Merit	is the value of the augmented Lagrangian merit function (12) at the current iterate. This function will decrease at each iteration unless it was necessary to increase the penalty parameters (see Section 8.2). As the solution is approached, Merit will converge to the value of the objective function at the solution.
	If the QP subproblem does not have a feasible point (signified by I at the end of the current output line), the merit function is a large multiple of the constraint violations, weighted by the penalty parameters. During a sequence of major iterations with infeasible subproblems, the

sequence of Merit values will decrease monotonically until either a feasible subproblem is obtained or E04UCF terminates with IFAIL = 3 (no feasible point could be found for the nonlinear constraints).

If no nonlinear constraints are present (i.e., NCNLN = 0), this entry contains Objective, the value of the objective function F(x). The objective function will decrease monotonically to its optimal value when there are no nonlinear constraints.

Bnd	is the number of simple bound constraints in the predicted active set.
Lin	is the number of general linear constraints in the predicted active set.
Nln	is the number of nonlinear constraints in the predicted active set (not printed if NCNLN is zero).
Nz	is the number of columns of Z (see Section 8.1). The value of Nz is the number of variables minus the number of constraints in the predicted active set; i.e., Nz = n-(Bnd + Lin + Nln).
Norm Gf	is the Euclidean norm of g_{FR}, the gradient of the objective function with respect to the free variables, i.e.,variables not currently held at a bound.
Norm Gz	is $\|\|Z^T g_{FR}\|\|$, the Euclidean norm of the projected gradient (see Section 8.1). Norm Gz will be approximately zero in the neighbourhood of a solution.
Cond H	is a lower bound on the condition number of the Hessian approximation H.
Cond Hz	is a lower bound on the condition number of the projected Hessian approximation H_z ($(H_z=Z^T H_{FR} Z=R^T_z R_z$; see (6) and (12) in Sections 3

```
                and 8.1). The larger this number, the more
                difficult the problem.

Cond T          is a lower bound on the condition number of the
                matrix of predicted active constraints.

Norm C          is the Euclidean norm of the residuals of
                constraints that are violated or in the predicted
                active set (not printed if NCNLN is zero). Norm C
                will be approximately zero in the neighbourhood of
                a solution.

Penalty         is the Euclidean norm of the vector of penalty
                parameters used in the augumented Lagrangian merit
                function (not printed if NCNLN is zero).

Conv            is a three-letter indication of the status of the
                three convergence tests (8a)-(8c) defined in the
                description of the optional parameter Optimality
                Tolerance in Section 5.1 Each letter is T if the
                test is satisfied, and F otherwise. The three
                tests indicate whether:
                (a)   the sequence of iterates has converged;

                (b)   the projected gradient (Norm  Gz) is
                      sufficiently small; and

                (c)   the norm of the residuals of constraints in
                      the predicted active set (Norm  C) is small
                      enough.
                If any of these indicators is F when E04UCF
                terminates with IFAIL = 0, the user should check
                the solution carefully.

M               is printed if the Quasi-Newton update was modified
                to ensure that the Hessian approximation is
                positive-definite (see Section 8.3).

I               is printed if the QP subproblem has no feasible
                point.

C               is printed if central differences were used to
                compute the unspecified objective and constraint
                gradients. If the value of Step is zero, the
                switch to central differences was made because no
                lower point could be found in the linesearch. (In
                this case, the QP subproblem is resolved with the
                central-difference gradient and Jacobian.) If the
                value of Step is non-zero, central differences
                were computed because Norm  Gz and Norm  C imply
```

	that x is close to a Kuhn-Tucker point.
L	is printed if the linesearch has produced a relative change in x greater than the value defined by the optional parameter Step Limit. If this output occurs frequently during later iterations of the run, Step Limit should be set to a larger value.
R	is printed if the approximate Hessian has been refactorized. If the diagonal condition estimator of R indicates that the approximate Hessian is badly conditioned, the approximate Hessian is refactorized using column interchanges. If necessary, R is modified so that its diagonal condition estimator is bounded.

When Major Print Level = 1 or Major Print Level >= 10, the summary printout at the end of execution of E04UCF includes a listing of the status of every variable and constraint. Note that default names are assigned to all variables and constraints.

The following describes the printout for each variable.

Varbl	gives the name (V) and index j=1,2,...,n of the variable.
State	gives the state of the variable in the predicted active set (FR if neither bound is in the active set, EQ if a fixed variable, LL if on its lower bound, UL if on its upper bound). If the variable is predicted to lie outside its upper or lower bound by more than the feasibility tolerance, State will be ++ or -- respectively. (The latter situation can occur only when there is no feasible point for the bounds and linear constraints.)
Value	is the value of the variable at the final iteration.
Lower bound	is the lower bound specified for the variable. (None indicates that BL(j)<=- BIGBND.)
Upper bound	is the upper bound specified for the variable. (None indicates that BL(j)>=BIGBND.)
Lagr Mult	is the value of the Lagrange-multiplier for the associated bound constraint. This will be zero if State is FR. If x is optimal, the multiplier should be non-negative if State is LL, and non-

```
               positive if State is UL.

Residual       is the difference between the variable Value and
               the nearer of its bounds BL(j) and BU(j).
```

The printout for general constraints is the same as for variables, except for the following:

```
L Con      is the name (L) and index i, for i = 1,2,...,NCLIN of
           a linear constraint.

N Con      is the name (N) and index i, for i = 1,2,...,NCNLN of
           a nonlinear constraint.
```

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

The input data for E04UCF should always be checked (even if E04UCF terminates with IFAIL=0).

Note that when Print Level>0, a short description of IFAIL is printed.

Errors and diagnostics indicated by IFAIL, together with some recommendations for recovery are indicated below.

IFAIL= 1

The final iterate x satisfies the first-order Kuhn-Tucker conditions to the accuracy requested, but the sequence of iterates has not yet converged. E04UCF was terminated because no further improvement could be made in the merit function.

This value of IFAIL may occur in several circumstances. The most common situation is that the user asks for a solution with accuracy that is not attainable with the given precision of the problem (as specified by Function Precision see Section 5). This condition will also occur if, by chance, an iterate is an 'exact' Kuhn-Tucker point, but the change in the variables was significant at the previous iteration. (This situation often happens when minimizing very simple functions, such as quadratics.)

If the four conditions listed in Section 5 for IFAIL = 0 are satisfied, x is likely to be a solution of (1) even if IFAIL = 1.

```
IFAIL= 2
     E04UCF has terminated without finding a feasible point for
     the linear constraints and bounds, which means that no
     feasible point exists for the given value of Linear
     Feasibility Tolerance (see Section 5.1). The user should
     check that there are no constraint redundancies. If the data
     for the constraints are accurate only to an absolute
     precision (sigma), the user should ensure that the value of
     the optional parameter Linear Feasibility Tolerance is
     greater than (sigma). For example, if all elements of A are
     of order unity and are accurate to only three decimal
                                                              -3
     places, Linear Feasibility Tolerance should be at least 10  .

IFAIL= 3
     No feasible point could be found for the nonlinear
     constraints. The problem may have no feasible solution. This
     means that there has been a sequence of QP subproblems for
     which no feasible point could be found (indicated by I at
     the end of each terse line of output). This behaviour will
     occur if there is no feasible point for the nonlinear
     constraints. (However, there is no general test that can
     determine whether a feasible point exists for a set of
     nonlinear constraints.) If the infeasible subproblems occur
     from the very first major iteration, it is highly likely
     that no feasible point exists. If infeasibilities occur when
     earlier subproblems have been feasible, small constraint
     inconsistencies may be present. The user should check the
     validity of constraints with negative values of ISTATE. If
     the user is convinced that a feasible point does exist,
     E04UCF should be restarted at a different starting point.

IFAIL= 4
     The limiting number of iterations (determined by the
     optional parameter Major Iteration Limit see Section 5.1)
     has been reached.

     If the algorithm appears to be making progress, Major
     Iteration Limit may be too small. If so, increase its value
     and rerun E04UCF (possibly using the Warm Start option). If
     the algorithm seems to be 'bogged down', the user should
     check for incorrect gradients or ill-conditioning as
     described below under IFAIL = 6.

     Note that ill-conditioning in the working set is sometimes
     resolved automatically by the algorithm, in which case
     performing additional iterations may be helpful. However,
     ill-conditioning in the Hessian approximation tends to
     persist once it has begun, so that allowing additional
     iterations without altering R is usually inadvisable. If the
     quasi-Newton update of the Hessian approximation was
     modified during the latter iterations (i.e., an M occurs at
     the end of each terse line), it may be worthwhile to try a
     warm start at the final point as suggested above.

IFAIL= 6
     x does not satisfy the first-order Kuhn-Tucker conditions,
     and no improved point for the merit function could be found
     during the final line search.

     A sufficient decrease in the merit function could not be
     attained during the final line search. This sometimes occurs
     because an overly stringent accuracy has been requested,
     i.e., Optimality Tolerance is too small. In this case the
     user should apply the four tests described under IFAIL = 0
     above to determine whether or not the final solution is
     acceptable (see Gill et al [10], for a discussion of the
     attainable accuracy).

     If many iterations have occurred in which essentially no
     progress has been made and E04UCF has failed completely to
     move from the initial point then subroutines OBJFUN or
     CONFUN may be incorrect. The user should refer to comments
     below under IFAIL = 7 and check the gradients using the
     Verify parameter. Unfortunately, there may be small errors
     in the objective and constraint gradients that cannot be
     detected by the verification process. Finite-difference
     approximations to first derivatives are catastrophically
     affected by even small inaccuracies. An indication of this
     situation is a dramatic alteration in the iterates if the
     finite-difference interval is altered. One might also
     suspect this type of error if a switch is made to central
     differences even when Norm Gz and Norm C are large.

     Another possibility is that the search direction has become
     inaccurate because of ill-conditioning in the Hessian
     approximation or the matrix of constraints in the working
     set; either form of ill-conditioning tends to be reflected
     in large values of ItQP (the number of iterations required
     to solve each QP subproblem).

     If the condition estimate of the projected Hessian (Cond Hz)
     is extremely large, it may be worthwhile to rerun E04UCF
     from the final point with the Warm Start option. In this
     situation, ISTATE should be left unaltered and R should be
     reset to the identity matrix.

     If the matrix of constraints in the working set is ill-
     conditioned (i.e., Cond T is extremely large), it may be
```

```
          helpful to run E04UCF with a relaxed value of the
          Feasibility Tolerance (Constraint dependencies are often
          indicated by wide variations in size in the diagonal
          elements of the matrix T, whose diagonals will be printed
          for Major Print Level >= 30).

     IFAIL= 7
          The user-provided derivatives of the objective function
          and/or nonlinear constraints appear to be incorrect.

          Large errors were found in the derivatives of the objective
          function and/or nonlinear constraints. This value of IFAIL
          will occur if the verification process indicated that at
          least one gradient or Jacobian component had no correct
          figures. The user should refer to the printed output to
          determine which elements are suspected to be in error.

          As a first-step, the user should check that the code for the
          objective and constraint values is correct - for example, by
          computing the function at a point where the correct value is
          known. However, care should be taken that the chosen point
          fully tests the evaluation of the function. It is remarkable
          how often the values x=0 or x=1 are used to test function
          evaluation procedures, and how often the special properties
          of these numbers make the test meaningless.

          Special care should be used in this test if computation of
          the objective function involves subsidiary data communicated
          in COMMON storage. Although the first evaluation of the
          function may be correct, subsequent calculations may be in
          error because some of the subsidiary data has accidently
          been overwritten.

          Errors in programming the function may be quite subtle in
          that the function value is 'almost' correct. For example,
          the function may not be accurate to full precision because
          of the inaccurate calculation of a subsidiary quantity, or
          the limited accuracy of data upon which the function
          depends. A common error on machines where numerical
          calculations are usually performed in double precision is to
          include even one single-precision constant in the
          calculation of the function; since some compilers do not
          convert such constants to double precision, half the correct
          figures may be lost by such a seemingly trivial error.

     IFAIL= 9
          An input parameter is invalid. The user should refer to the
          printed output to determine which parameter must be
          redefined.
```

IFAILOverflow

If the printed output before the overflow error contains a warning about serious ill-conditioning in the working set when adding the jth constraint, it may be possible to avoid the difficulty by increasing the magnitude of the optional parameter Linear Feasiblity Tolerance or Nonlinear Feasiblity Tolerance, and rerunning the program. If the message recurs even after this change, the offending linearly dependent constraint (with index 'j') must be removed from the problem. If overflow occurs in one of the user-supplied routines (e.g. if the nonlinear functions involve exponentials or singularities), it may help to specify tighter bounds for some of the variables (i.e., reduce the gap between appropriate l_j and u_j).

7. Accuracy

If IFAIL = 0 on exit then the vector returned in the array X is an estimate of the solution to an accuracy of approximately Feasiblity Tolerance (see Section 5.1), whose default value is $(epsilon)^{0.8}$, where (epsilon) is the machine precision (see X02AJF(*)).

8. Further Comments

In this section we give some further details of the method used by E04UCF.

8.1. Solution of the Quadratic Programming Subproblem

The search direction p is obtained by solving (4) using the method of E04NCF(*) (Gill et al [8]), which was specifically designed to be used within an SQP algorithm for nonlinear programming.

The method of E04UCF is a two-phase (primal) quadratic programming method. The two phases of the method are: finding an initial feasible point by minimizing the sum of infeasibilities (the feasibility phase), and minimizing the quadratic objective function within the feasible region (the optimality phase). The computations in both phases are perfomed by the same subroutines. The two-phase nature of the algorithm is reflected by changing the function being minimized from the sum of infeasibilities to the quadratic objective function.

In general, a quadratic program must be solved by iteration. Let $\bar{p}$ denote the current estimate of the solution of (4); the new iterate p is defined by

$$\bar{p}=p+\sigma d, \tag{9}$$

where, as in (3), (sigma) is a non-negative step length and d is a search direction.

At the beginning of each iteration of E04UCF, a working set is defined of constraints (general and bound) that are satisfied exactly. The vector d is then constructed so that the values of constraints in the working set remain unaltered for any move along d. For a bound constraint in the working set, this property is achieved by setting the corresponding component of d to zero, i.e., by fixing the variable at its bound. As before, the subscripts 'FX' and 'FR' denote selection of the components associated with the fixed and free variables.

Let C denote the sub-matrix of rows of

$$\begin{pmatrix} A_L \\ A_N \end{pmatrix}$$

corresponding to general constraints in the working set. The general constraints in the working set will remain unaltered if

$$C_{FR} d_{FR} =0, \tag{10}$$

which is equivalent to defining d_{FR} as

$$d_{FR} =Zd_z \tag{11}$$

for some vector d_z, where Z is the matrix associated with the TQ factorization (5) of C_{FR}.

The definition of d_z in (11) depends on whether the current p is feasible. If not, d_z is zero except for a component (gamma) in the jth position, where j and (gamma) are chosen so that the sum of infeasibilities is decreasing along d. (For further details, see Gill et al [8].) In the feasible case, d_z satisfies the equations

$$R_z^T R_z d_z = -Z^T q_{FR} , \qquad (12)$$

where R_z is the Cholesky factor of $Z^T H_{FR} Z$ and q is the gradient of the quadratic objective function (q=g+Hp). (The vector $Z^T q_{FR}$ is the projected gradient of the QP.) With (12), P+d is the minimizer of the quadratic objective function subject to treating the constraints in the working set as equalities.

If the QP projected gradient is zero, the current point is a constrained stationary point in the subspace defined by the working set. During the feasiblity phase, the projected gradient will usually be zero only at a vertex (although it may vanish at non-vertices in the presence of constraint dependencies). During the optimality phase, a zero projected gradient implies that p minimizes the quadratic objective function when the constraints in the working set are treated as equalities. In either case, Lagrange multipliers are computed. Given a positive constant (delta) of the order of the machine precision, the Lagrange multiplier $(mu)_j$ corresponding to an inequality constraint in the working set at its upper bound is said to be optimal if $(mu)_j$ <=(delta) when the jth constraint is at its upper bound, or if $(mu)_j$ >=-(delta) when the associated constraint is at its lower bound. If any multiplier is non-optimal, the current objective function (either the true objective or the sum of infeasibilities) can be reduced by deleting the corresponding constraint from the working set.

If optimal multipliers occur during the feasibility phase and the sum of infeasibilities is non-zero, no feasible point exists. The QP algorithm will then continue iterating to determine the minimum sum of infeasibilities. At this point, the Lagrange multiplier $(mu)_j$ will satisfy -(1+(delta))<=$(mu)_j$ <=(delta) for an inequality constraint at its upper bound, and -(delta)<=$(mu)_j$ <=1+(delta) for an inequality at its lower bound. The Lagrange multiplier for an equality constraint will satisfy |$(mu)_j$ |<=1+(delta).

The choice of step length σ in the QP iteration (9) is based on remaining feasible with respect to the satisfied constraints. During the optimality phase, if p+d is feasible, σ will be taken as unity. (In this case, the projected gradient at $\bar{p}$ will be zero.) Otherwise, σ is set to σ_M, the step to the 'nearest'constraint, which is added to the working set at the next iteration.

Each change in the working set leads to a simple change to C_{FR}: if the status of a general constraint changes, a row of C_{FR} is altered; if a bound constraint enters or leaves the working set, a column of C_{FR} changes. Explicit representations are recurred of the matrices T, Q_{FR} and R, and of the vectors $Q^T q$ and $Q^T g$.

8.2. The Merit Function

After computing the search direction as described in Section 3, each major iteration proceeds by determining a step length α in (3) that produces a 'sufficient decrease' in the augmented Lagrangian merit function

$$L(x,\lambda,s)=F(x)-\sum_i \lambda_i (c_i(x)-s_i) + \frac{1}{2}\sum_i \rho_i (c_i(x)-s_i)^2, \qquad (13)$$

where x, λ and s vary during the linsearch. The summation terms in (13) involve only the nonlinear constraints. The vector λ is an estimate of the Lagrange multipliers for the nonlinear constraints of (1). The non-negative slack variables $\{s_i\}$ allow nonlinear inequality constraints to be treated without introducing discontinuities. The solution of the QP subproblem (4) provides a vector triple that serves as a direction of search for the three sets of variables. The non-negative vector ρ of penalty parameters is initialised to zero at the beginning of the first major iteration. Thereafter, selected components are increased whenever necessary to ensure descent for the merit function. Thus, the sequence of norms of (rho) (the printed quantity Penalty, see Section 5.2) is generally non-decreasing, although each $(rho)_i$ may be reduced a limited number of times.

The merit function (13) and its global convergence properties are described in Gill et al [9].

8.3. The Quasi-Newton Update

The matrix H in (4) is a positive-definite quasi-Newton approximation to the Hessian of the Lagrangian function. (For a review of quasi-Newton methods, see Dennis and Schnabel [3].) At the end of each major iteration, a new Hessian approximation $\bar{H}$ is defined as a rank-two modification of H. In E04UCF, the BFGS quasi-Newton update is used:

$$\bar{H}=H-\frac{1}{s^THs}Hss^TH+\frac{1}{y^Ts}yy^T, \qquad (14)$$

where $s=\bar{x}-x$ (the change in x).

In E04UCF, H is required to be positive-definite. If H is positive-definite, $\bar{H}$ defined by (14) will be positive-definite if and only if y^Ts is positive (see, e.g. Dennis and More [1]). Ideally, y in (14) would be taken as y_L, the change in gradient of the Lagrangian function

$$y_L=\bar{g}-\bar{A}_N^T(mu)_N-g+A_N^T(mu)_N, \qquad (15)$$

where $(mu)_N$ denotes the QP multipliers associated with the nonlinear constraints of the original problem. If y_L^Ts is not sufficiently positive, an attempt is made to perform the update with a vector y of the form

m

$$y=y_L + \sum_{i=1}^{N} \omega_i (a_i(\bar{x})c_i(\bar{x})-a_i(x)c_i(x)),$$

where $\omega_i \geq 0$. If no such vector can be found, the update is perfomed with a scaled y_L; in this case, M is printed to indicate that the update is modified.

Rather than modifying H itself, the Cholesky factor of the transformed Hessian H_Q (6) is updated, where Q is the matrix from (5) associated with the active set of the QP subproblem. The update (13) is equivalent to the following update to H_Q:

$$\bar{H}_Q = H_Q - \frac{1}{s_Q^T H_Q s_Q} H_Q s_Q s_Q^T H_Q + \frac{1}{y_Q^T s_Q} y_Q y_Q^T, \qquad (16)$$

where $y_Q=Q^T y$, and $s_Q=Q^T s$. This update may be expressed as a rank-one update to R (see Dennis and Schnabel [2]).

9. Example

This section describes one version of the so-called 'hexagon' problem (a different formulation is given as Problem 108 in Hock and Schittkowski [11]). The problem is to determine the hexagon of maximum area such that no two of its vertices are more than one unit apart (the solution is not a regular hexagon).

All constraint types are included (bounds, linear, nonlinear), and the Hessian of the Lagrangian function is not positive-definite at the solution. The problem has nine variables, non-infinite bounds on seven of the variables, four general linear constraints, and fourteen nonlinear constraints.

The objective function is

$$F(x)=-x_2x_6+x_1x_7-x_3x_7-x_5x_8+x_4x_9+x_3x_8.$$

The bounds on the variables are

$x_1 >= 0$, $-1 <= x_3 <= 1$, $x_5 >= 0, x_6 >= 0$, $x_7 >= 0, x_8 <= 0$, and $x_9 <= 0$.

Thus,

$$l_B = (0,-infty,-1,-infty,0,0,0,-infty,-infty)^T$$

$$u_B = (infty,infty,1,infty,infty,infty,infty,0,0)^T$$

The general linear constraints are

$x_2 - x_1 >= 0, x_3 - x_2 >= 0$, $x_3 - x_4 >= 0$, and $x_4 - x_5 >= 0$.

Hence,

$$l_L = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}, A_L = \begin{pmatrix} -1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & -1 & 0 & 0 & 0 & 0 \end{pmatrix} \text{ and } u_L = \begin{pmatrix} infty \\ infty \\ infty \\ infty \end{pmatrix}.$$

The nonlinear constraints are all of the form $c_i(x) <= 1$, for $i=1,2,...,14$; hence, all components of l_N are -infty, and all components of u_N are 1. The fourteen functions $\{c_i(x)\}$ are

$$c_1(x) = x_1^2 + x_6^2,$$

$$c_2(x) = (x_2 - x_1)^2 + (x_7 - x_6)^2,$$

$$c_3(x) = (x_3 - x_1)^2 + x_6^2,$$

$$c_4(x) = (x_1 - x_4)^2 + (x_6 - x_8)^2,$$

2 2

$$c_5(x)=(x_1-x_5)^2+(x_6-x_9)^2,$$

$$c_6(x)=x_2^2+x_7^2,$$

$$c_7(x)=(x_3-x_2)^2+x_7^2,$$

$$c_8(x)=(x_4-x_2)^2+(x_8-x_7)^2,$$

$$c_9(x)=(x_2-x_5)^2+(x_7-x_9)^2,$$

$$c_{10}(x)=(x_4-x_3)^2+x_8^2,$$

$$c_{11}(x)=(x_5-x_3)^2+x_9^2,$$

$$c_{12}(x)=x_4^2+x_8^2,$$

$$c_{13}(x)=(x_4-x_5)^2+(x_9-x_8)^2,$$

$$c_{14}(x)=x_5^2+x_9^2.$$

An optimal solution (to five figures) is

$$x^*=(0.060947,0.59765,1.0,0.59765,0.060947,0.34377,0.5,$$
$$-0.5,0.34377)^T,$$

and $F(x^*)=-1.34996$. (The optimal objective function is unique, but is achieved for other values of x.) Five nonlinear constraints and one simple bound are active at x^*. The sample solution output is given later in this section, following the sample main program and problem definition.

Two calls are made to E04UCF in order to demonstrate some of its features. For the first call, the starting point is:

$$x_0 =(0.1,0.125,0.666666,0.142857,0.111111,0.2,0.25,-0.2,-0.25)^T .$$

All objective and constraint derivatives are specified in the user-provided subroutines OBJFN1 and CONFN1, i.e., the default option Derivative Level =3 is used.

On completion of the first call to E04UCF, the optimal variables are perturbed to produce the initial point for a second run in which the problem functions are defined by the subroutines OBJFN2 and CONFN2. To illustrate one of the finite-difference options in E04UCF, these routines are programmed so that the first six components of the objective gradient and the constant elements of the Jacobian matrix are not specified; hence, the option Derivative Level =0 is chosen. During computation of the finite-difference intervals, the constant Jacobian elements are identified and set, and E04UCF automatically increases the derivative level to 2.

The second call to E04UCF illustrates the use of the Warm Start Level option to utilize the final active set, nonlinear multipliers and approximate Hessian from the first run. Note that Hessian = Yes was specified for the first run so that the array R would contain the Cholesky factor of the approximate Hessian of the Lagrangian.

The two calls to E04UCF illustrate the alternative methods of assigning default parameters. (There is no special significance in the order of these assignments; an options file may just as easily be used to modify parameters set by E04UEF.)

The results are typical of those obtained from E04UCF when solving well behaved (non-trivial) nonlinear problems. The approximate Hessian and working set remain relatively well-conditioned. Similarly the penalty parameters remain small and approximately constant. The numerical results illustrate much of the theoretically predicted behaviour of a quasi-Newton SQP method. As x approaches the solution, only one minor iteration is perfomed per major iteration, and the Norm Gz and Norm C columns exhibit the fast linear convergence rate mentioned in Sections 5 and 6. Note that the constraint violations converge earlier than

```
        the projected gradient. The final values of the project gradient
        norm and constraint norm reflect the limiting accuracy of the two
        quantities. It is possible to achieve almost full precision in
        the constraint norm but only half precision in the projected
        gradient norm. Note that the final accuracy in the nonlinear
        constraints is considerably better than the feasibility
        tolerance, because the constraint violations are being refined
        during the last few iterations while the algorithm is working to
        reduce the projected gradient norm. In this problem, the
        constraint values and Lagrange multipliers at the solution are '
        well balanced', i.e., all the multipliers are approximately the
        same order of magnitude. The behaviour is typical of a well-
        scaled problem.

        The example program is not reproduced here. The source code for
        all example programs is distributed with the NAG Foundation
        Library software and should be available on-line.

\begin{verbatim}

     E04UDF(3NAG)      Foundation Library (12/10/92)      E04UDF(3NAG)

          E04 -- Minimizing or Maximizing a Function                E04UDF
                  E04UDF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose
```

To supply optional parameters to E04UCF from an external file.

2. Specification

```
       SUBROUTINE E04UDF (IOPTNS, INFORM)
       INTEGER          IOPTNS, INFORM
```

3. Description

E04UDF may be used to supply values for optional parameters to E04UCF. E04UDF reads an external file and each line of the file defines a single optional parameter. It is only necessary to supply values for those parameters whose values are to be different from their default values.

Each optional parameter is defined by a single character string of up to 72 characters, consisting of one or more items. The items associated with a given option must be separated by spaces, or equal signs (=). Alphabetic characters may be upper or lower case. The string

```
       Print level = 1
```

is an example of a string used to set an optional parameter. For each option the string contains one or more of the following items:

(a)   A mandatory keyword.

(b)   A phrase that qualifies the keyword.

(c)   A number that specifies an INTEGER or real value. Such numbers may be up to 16 contiguous characters in Fortran 77's I, F, E or D formats, terminated by a space if this is not the last item on the line.

Blank strings and comments are ignored. A comment begins with an asterisk (*) and all subsequent characters in the string are regarded as part of the comment.

The file containing the options must start with begin and must finish with end An example of a valid options file is:

```
      Begin * Example options file
       Print level =10
      End
```

Normally each line of the file is printed as it is read, on the current advisory message unit (see X04ABF), but printing may be suppressed using the keyword nolist To suppress printing of begin,

```
nolist must be the first option supplied as in the file:

      Begin
        Nolist
        Print level = 10
      End

Printing will automatically be turned on again after a call to
E04UCF and may be turned on again at any time by the user by
using the keyword list.

Optional parameter settings are preserved following a call to
E04UCF, and so the keyword defaults is provided to allow the user
to reset all the optional parameters to their default values
prior to a subsequent call to E04UCF.

A complete list of optional parameters, their abbreviations,
synonyms and default values is given in Section 5.1 of the
document for E04UCF.

4. References

None.

5. Parameters

 1:  IOPTNS -- INTEGER                                      Input
     On entry: IOPTNS must be the unit number of the options
     file. Constraint: 0 <= IOPTNS <= 99.

 2:  INFORM -- INTEGER                                     Output
     On exit: INFORM will be zero, if an options file with the
     current structure has been read. Otherwise INFORM will be
     positive. Positive values of INFORM indicate that an options
     file may not have been successfully read as follows:
     INFORM = 1
           IOPTNS is not in the range [0,99].

     INFORM = 2
           begin was found, but end-of-file was found before end
           was found.

     INFORM = 3
           end-of-file was found before begin was found.

6. Error Indicators and Warnings

If a line is not recognised as a valid option, then a warning
message is output on the current advisory message unit (X04ABF).
```

```
          7. Accuracy

          Not applicable.

          8. Further Comments

          E04UEF may also be used to supply optional parameters to E04UCF.

          9. Example

          See the example for E04UCF.

16.4.42 Supply individual optional params to E04UCF

— nage.ht —

```
\begin{page}{manpageXXe04uef}{NAG Documentation: e04uef}
\beginscroll
\begin{verbatim}

     E04UEF(3NAG)      Foundation Library (12/10/92)      E04UEF(3NAG)

          E04 -- Minimizing or Maximizing a Function                 E04UEF
                  E04UEF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          To supply individual optional parameters to E04UCF.

          2. Specification

                 SUBROUTINE E04UEF (STRING)
```

```
       CHARACTER*(*)    STRING
```

3. Description

E04UEF may be used to supply values for optional parameters to E04UCF. It is only necessary to call E04UEF for those parameters whose values are to be different from their default values. One call to E04UEF sets one parameter value.

Each optional parameter is defined by a single character string of up to 72 characters, consisting of one or more items. The items associated with a given option must be separated by spaces, or equal signs (=). Alphabetic characters may be upper or lower case. The string

```
      Print level = 1
```

is an example of a string used to set an optional parameter. For each option the string contains one or more of the following items:

(a) A mandatory keyword.

(b) A phrase that qualifies the keyword.

(c) A number that specifies an INTEGER or real value. Such numbers may be up to 16 contiguous characters in Fortran 77's I, F, E or D formats, terminated by a space if this is not the last item on the line.

Blank strings and comments are ignored. A comment begins with an asterisk (*) and all subsequent characters in the string are regarded as part of the comment.

Normally, each user-specified option is printed as it is defined, on the current advisory message unit (see X04ABF), but this printing may be suppressed using the keyword nolist Thus the statement

```
      CALL E04UEF ('Nolist')
```

suppresses printing of this and subsequent options. Printing will automatically be turned on again after a call to E04UCF, and may be turned on again at any time by the user, by using the keyword list.

Optional parameter settings are preserved following a call to E04UCF, and so the keyword defaults is provided to allow the user to reset all the optional parameters to their default values by the statement,

```
                CALL E04UEF ('Defaults')

          prior to a subsequent call to E04UCF.

          A complete list of optional parameters, their abbreviations,
          synonyms and default values is given in Section 5.1 of the
          document for E04UCF.

          4. References

          None.

          5. Parameters

           1:  STRING -- CHARACTER*(*)                              Input
               On entry: STRING must be a single valid option string. See
               Section 3 above and Section 5.1 of the routine document for
               E04UCF. On entry: STRING must be a single valid option
               string. See Section 3 above and Section 5.1 of the routine
               document for E04UCF.

          6. Error Indicators and Warnings

          If the parameter STRING is not recognised as a valid option
          string, then a warning message is output on the current advisory
          message unit (X04ABF).

          7. Accuracy

          Not applicable.

          8. Further Comments

          E04UDF may also be used to supply optional parameters to E04UCF.

          9. Example

          See the example for E04UCF.

```

16.4.43 Estimates of elements of the variance-covariance matrix

— nage.ht —

```
\begin{page}{manpageXXe04ycf}{NAG Documentation: e04ycf}
\beginscroll
\begin{verbatim}

     E04YCF(3NAG)      Foundation Library (12/10/92)      E04YCF(3NAG)

          E04 -- Minimizing or Maximizing a Function                E04YCF
                  E04YCF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          E04YCF returns estimates of elements of the variance-covariance
          matrix of the estimated regression coefficients for a nonlinear
          least squares problem. The estimates are derived from the
          Jacobian of the function f(x) at the solution.

          This routine may be used following any one of the nonlinear
          least-squares routines E04FCF(*), E04FDF, E04GBF(*), E04GCF,
          E04GDF(*), E04GEF(*), E04HEF(*), E04HFF(*).

          2. Specification

                 SUBROUTINE E04YCF (JOB, M, N, FSUMSQ, S, V, LV, CJ, WORK,
                1                   IFAIL)
                 INTEGER          JOB, M, N, LV, IFAIL
                 DOUBLE PRECISION FSUMSQ, S(N), V(LV,N), CJ(N), WORK(N)

          3. Description

          E04YCF is intended for use when the nonlinear least-squares
                          T
          function, F(x)=f (x)f(x), represents the goodness of fit of a
          nonlinear model to observed data. The routine assumes that the
          Hessian of F(x), at the solution, can be adequately approximated
               T
          by 2J J, where J is the Jacobian of f(x) at the solution. The
```

estimated variance-covariance matrix C is then given by

$$C=\sigma^2 (J^T J)^{-1} \quad J^T J \text{ non-singular},$$

where σ^2 is the estimated variance of the residual at the

solution, x, given by

$$\sigma^2 = \frac{F(x)}{m-n},$$

m being the number of observations and n the number of variables.

The diagonal elements of C are estimates of the variances of the estimated regression coefficients. See the Chapter Introduction E04 and Bard [1] and Wolberg [2] for further information on the use of C.

When $J^T J$ is singular then C is taken to be

$$C=\sigma^2 (J^T J)^*,$$

where $(J^T J)^*$ is the pseudo-inverse of $J^T J$, but in this case the parameter IFAIL is returned as non-zero as a warning to the user that J has linear dependencies in its columns. The assumed rank of J can be obtained from IFAIL.

The routine can be used to find either the diagonal elements of C, or the elements of the jth column of C, or the whole of C.

E04YCF must be preceded by one of the nonlinear least-squares routines mentioned in Section 1, and requires the parameters FSUMSQ, S and V to be supplied by those routines. FSUMSQ is the

residual sum of squares F(x), and S and V contain the singular values and right singular vectors respectively in the singular value decomposition of J. S and V are returned directly by the comprehensive routines E04FCF(*), E04GBF(*), E04GDF(*) and E04HEF(*), but are returned as part of the workspace parameter W from the easy-to-use routines E04FDF, E04GCF, E04GEF(*) and

E04HFF(*). In the case of E04FDF, S starts at W(NS), where

```
               NS=6*N+2*M+M*N+1+max(1,N*(N-1)/2)
```

and in the cases of the remaining easy-to-use routines, S starts at W(NS), where

```
          NS=7*N+2*M+M*N+N*(N+1)/2+1+max(1,N*(N-1)/2)
```

The parameter V starts immediately following the elements of S, so that V starts at W(NV), where

```
                            NV=NS+N.
```

For all the easy-to-use routines the parameter LV must be supplied as N. Thus a call to E04YCF following E04FDF can be illustrated as

```
       CALL E04FDF (M, N, X, FSUMSQ, IW, LIW, W, LW, IFAIL)
       NS = 6*N + 2*M + M*N + 1 + MAX((1,(N*(N-1))/2)
       NV = NS + N
       CALL E04YCF (JOB, M, N, FSUMSQ, W(NS), W(NV),
      *             N, CJ, WORK, IFAIL)
```

where the parameters M, N, FSUMSQ and the $(n+n^2)$ elements W(NS), WS(NS+1),..., W(NV+N*N-1) must not be altered between the calls to E04FDF and E04YCF. The above illustration also holds for a call to E04YCF following a call to one of E04GCF, E04GEF(*), E04HFF(*) except that NS must be computed as

```
      NS = 7*N + 2*M + M*N + (N*(N+1))/2 + 1 + MAX((1,N*(N-1))/2)
```

4. References

[2] Wolberg J R (1967) Prediction Analysis. Van Nostrand.

5. Parameters

1: JOB -- INTEGER   Input
    On entry: which elements of C are returned as follows:
    JOB = -1
          The n by n symmetric matrix C is returned.

    JOB = 0
          The diagonal elements of C are returned.

```
    JOB > 0
          The elements of column JOB of C are returned.
     Constraint: -1 <= JOB <= N.

2:  M -- INTEGER                                       Input
    On entry: the number m of observations (residuals f (x)).
                                                       i
    Constraint: M >= N.

3:  N -- INTEGER                                       Input
    On entry: the number n of variables (x ). Constraint: 1 <=
                                          j
    N <= M.

4:  FSUMSQ -- DOUBLE PRECISION                         Input

    On entry: the sum of squares of the residuals, F(x), at the

    solution x, as returned by the nonlinear least-squares
    routine. Constraint: FSUMSQ >= 0.0.

5:  S(N) -- DOUBLE PRECISION array                     Input
    On entry: the n singular values of the Jacobian as returned
    by the nonlinear least-squares routine. See Section 3 for
    information on supplying S following one of the easy-to-use
    routines.

6:  V(LV,N) -- DOUBLE PRECISION array           Input/Output
    On entry: the n by n right-hand orthogonal matrix (the
    right singular vectors) of J as returned by the nonlinear
    least-squares routine. See Section 3 for information on
    supplying V following one of the easy-to-use routines. On
    exit: when JOB >= 0 then V is unchanged.

    When JOB = -1 then the leading n by n part of V is
    overwritten by the n by n matrix C. When E04YCF is called
    with JOB = -1 following an easy-to-use routine this means
                                                    2
    that C is returned, column by column, in the n  elements of
                                             2
    W given by W(NV),W(NV+1),...,W(NV+N -1). (See Section 3 for
    the definition of NV).

7:  LV -- INTEGER                                      Input
    On entry:
    the first dimension of the array V as declared in the
    (sub)program from which E04YCF is called.
```

```
     When V is passed in the workspace parameter W following one
     of the easy-to-use least-square routines, LV must be the
     value N.

 8:  CJ(N) -- DOUBLE PRECISION array                      Output
     On exit: with JOB = 0, CJ returns the n diagonal elements
     of C.

     With JOB = j>0, CJ returns the n elements of the jth column
     of C.

     When JOB = -1, CJ is not referenced.

 9:  WORK(N) -- DOUBLE PRECISION array                 Workspace
     When JOB = -1 or 0 then WORK is used as internal workspace.

     When JOB > 0, WORK is not referenced.

10:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. Users who are
     unfamiliar with this parameter should refer to the Essential
     Introduction for details.

     On exit: IFAIL = 0 unless the routine detects an error or
     gives a warning (see Section 6).

     For this routine, because the values of output parameters
     may be useful even if IFAIL /=0 on exit, users are
     recommended to set IFAIL to -1 before entry. It is then
     essential to test the value of IFAIL on exit. To suppress
     the output of an error message when soft failure occurs, set
     IFAIL to 1.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

IFAIL= 1
     On entry JOB < -1,

     or       JOB > N,

     or       N < 1,

     or       M < N,

     or       FSUMSQ < 0.0.

IFAIL= 2
     The singular values are all zero, so that at the solution
```

the Jacobian matrix J has rank 0.

IFAIL> 2
At the solution the Jacobian matrix contains linear, or near linear, dependencies amongst its columns. In this case the required elements of C have still been computed based upon J having an assumed rank given by (IFAIL-2). The rank is computed by regarding singular values SV(j) that are not larger than 10*(epsilon)*SV(1) as zero, where (epsilon) is the machine precision (see X02AJF(*)). Users who expect near linear dependencies at the solution and are happy with this tolerance in determining rank should call E04YCF with IFAIL = 1 in order to prevent termination by P01ABF(*). It is then essential to test the value of IFAIL on exit from E04YCF.

IFAILOverflow
If overflow occurs then either an element of C is very large, or the singular values or singular vectors have been incorrectly supplied.

7. Accuracy

The computed elements of C will be the exact covariances corresponding to a closely neighbouring Jacobian matrix J.

8. Further Comments

When JOB = -1 the time taken by the routine is approximately proportional to n^3. When JOB >= 0 the time taken by the routine is approximately proportional to n^2.

9. Example

To estimate the variance-covariance matrix C for the least-squares estimates of x_1, x_2 and x_3 in the model

$$y=x_1+\frac{t_1}{x_2 t_2+x_3 t_3}$$

using the 15 sets of data given in the following table:

y	t_1	t_2	t_3
0.14	1.0	15.0	1.0

```
                                 0.18  2.0 14.0 2.0
                                 0.22  3.0 13.0 3.0
                                 0.25  4.0 12.0 4.0
                                 0.29  5.0 11.0 5.0
                                 0.32  6.0 10.0 6.0
                                 0.35  7.0  9.0 7.0
                                 0.39  8.0  8.0 8.0
                                 0.37  9.0  7.0 7.0
                                 0.58 10.0  6.0 6.0
                                 0.73 11.0  5.0 5.0
                                 0.96 12.0  4.0 4.0
                                 1.34 13.0  3.0 3.0
                                 2.10 14.0  2.0 2.0
                                 4.39 15.0  1.0 1.0

          The program uses (0.5,1.0,1.5) as the initial guess at the
          position of the minimum and computes the least-squares solution
          using E04FDF. See the routine document E04FDF for further
          information.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

Chapter F
Linear Algebra

1. Introduction

The F Chapters of the Library are concerned with linear algebra and cover a large area. This general introduction is intended to help users decide which particular F Chapter is relevant to their problem. There are F Chapters with the following titles:

F01 -- Matrix Factorizations

F02 -- Eigenvalues and Eigenvectors

F04 -- Simultaneous Linear Equations

F06 -- Linear Algebra Support Routines

F07 -- Linear Equations (LAPACK)

The principal problem areas addressed by the above Chapters are:

Systems of linear equations

Linear least-squares problems

Eigenvalue and singular value problems

The solution of these problems usually involves several matrix operations, such as a matrix factorization followed by the solution of the factorized form, and the routines for these operations themselves utilize lower level support routines; typically routines from Chapter F06. Most users will not normally need to be concerned with these support routines.

NAG has been involved in a project, called LAPACK [1], to develop a linear algebra package for modern high-performance computers and some of the routines developed within that project are incorporated into the Library as Chapter F07. It should be emphasised that, while the LAPACK project has been concerned with high-performance computers, the routines do not compromise efficiency on conventional machines.

For background information on numerical algorithms for the solution of linear algebra problems see Golub and Van Loan [4]. For some problem areas the user has the choice of selecting a single routine to solve the problem, a so-called Black Box routine, or selecting more than one routine to solve the problem, such as a factorization routine followed by a solve routine, so-called General Purpose routines. The following sections indicate which chapters are relevant to particular problem areas.

2. Linear Equations

The Black Box routines for solving linear equations of the form

$$Ax=b \quad \text{and} \quad AX=B,$$

where A is an n by n real or complex, non-singular matrix, are to be found in Chapter F04. Such equations can also be solved by selecting a General Purpose factorization routine from Chapter F01 and combining it with a solve routine in Chapter F04, or by selecting a factorization and a solve routine from Chapter F07.

There are routines to cater for a variety of types of matrix, including general, symmetric or Hermitian, symmetric or Hermitian positive definite, tridiagonal, skyline and sparse matrices.

In order to select the appropriate routine, users are recommended to consult the F04 Chapter Introduction in the first instance.

3. Linear Least-squares

Routines for solving linear least-squares problems of the form

$$\underset{x}{\text{minimize}}\ r^T r, \quad \text{where} \quad r=b-Ax,$$

where A is an m by n, possibly rank deficient, matrix are to be found in Chapter F04. Linear least-squares problems can also be solved by routines in the statistical Chapter G02.

In order to select the appropriate routine, users are recommended to consult the F04 Chapter Introduction in the first instance, but users with additional statistical requirements may prefer to consult the G02 Chapter Introduction.

4. Eigenvalue Problems and Singular Value Problems

Routines for solving standard matrix eigenvalue problems of the form

$$Ax=(\lambda)x,$$

where A is an n by n real or complex matrix, and generalized matrix eigenvalue problems of the form

Ax=(lambda)Bx

where B is also an n by n matrix are to be found in Chapter F02.

There are routines to cater for various types of matrices, including general, symmetric or Hermitian and sparse matrices.

Similarly, the routines for finding singular values and/or singular vectors of an m by n real or complex matrix A are to be found in Chapter F02.

In order to select the appropriate routine, users are recommended to consult the F02 Chapter Introduction in the first instance.

5. Matrix Factorizations

Routines for various sorts of matrix factorization are to be found in Chapters F01 and F07 together with associated transformation routines. In order to select the appropriate routine users are recommended to consult the F01 Chapter Introduction in the first instance.

6. Support Routines

Chapter F06 contains a variety of routines to perform elementary algebraic operations involving scalars, vectors and matrices, such as setting up a plane rotation, performing a dot product and computing a matrix-vector product. Chapter F06 contains routines that meet the specification of the BLAS (Basic Linear Algebra Subprograms) [5, 3, 2]. The routines in this chapter will not normally be required by the general user, but are intended for use by those who require to build specialist linear algebra modules. The BLAS are extensively used by other NAG Foundation Library routines.

                          Chapter F01
                      Matrix Factorization
```

1. Scope of the Chapter

This chapter provides facilities for matrix factorizations and associated transformations.

2. Background to the Problems

An n by n matrix may be factorized as

$$A=PLUQ^T,$$

where L and U are respectively lower and uper triangular matrices, and P and Q are permutation matrices. This is called an LU factorization. For general dense matrices it is usual to choose Q=I and to then choose P to ensure that the factorization is numerically stable. For sparse matrices, judicious choice of P and Q ensures numerical stability as well as maintaining as much sparsity as possible in the factors L and U. The LU factorization is normally used in connection with the solution of the linear equations

$$Ax=b,$$

whose solution, x, may then be obtained by solving in succession the simpler equations

$$Ly=P^T b, \quad Uz=y, \quad x=Qz$$

the first by forward substitution and the second by backward substitution. Routines to perform this solution are to be found in Chapter F04.

When A is symmetric positive-definite then we can choose $U=L^T$ and Q=P, to give the Cholesky factorization. This factorization is numerically stable without permutations, but in the sparse case the permutations can again be used to try to maintain sparsity. The Cholesky factorization is sometimes expressed as

$$A=PLDL^T P^T,$$

where D is a diagonal matrix with positive diagonal elements and

L is unit lower triangular.

The LU factorization can also be performed on rectangular matrices, but in this case it is more usual to perform a QR factorization. When A is an m by n (m>=n) matrix this is given by

```
      (R)
  A=Q(0),
```

where R is an n by n upper triangular matrix and Q is an orthogonal (unitary in the complex case) matrix.

3. Recommendations on Choice and Use of Routines

Routine F07ADF performs the LU factorization of a real m by n dense matrix.

The LU factorization of a sparse matrix is performed by routine F01BRF. Following the use of F01BRF, matrices with the same sparsity pattern may be factorized by routine F01BSF.

The Cholesky factorization of a real symmetric positive-definite dense matrix is performed by routine F07FDF.

Routine F01MCF performs the Cholesky factorization of a real symmetric positive-definite variable band (skyline) matrix, and a general sparse symmetric positive-definite matrix may be factorized using routine F01MAF.

The QR factorization of an m by n (m>=n) matrix is performed by routine F01QCF in the real case, and F01RCF in the complex case. Following the use of F01QCF, operations with Q may be performed using routine F01QDF and some, or all, of the columns of Q may be formed using routine F01QEF. Routines F01RDF and F01REF perform the same tasks following the use of F01RCF.

     F01BRF(3NAG)      Foundation Library (12/10/92)      F01BRF(3NAG)

        F01 -- Matrix Factorizations                            F01BRF
                F01BRF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F01BRF factorizes a real sparse matrix. The routine either forms the LU factorization of a permutation of the entire matrix, or, optionally, first permutes the matrix to block lower triangular form and then only factorizes the diagonal blocks.

2. Specification

```
       SUBROUTINE F01BRF (N, NZ, A, LICN, IRN, LIRN, ICN, PIVOT,
      1                   IKEEP, IW, W, LBLOCK, GROW, ABORT,
      2                   IDISP, IFAIL)
       INTEGER          N, NZ, LICN, IRN(LIRN), LIRN, ICN(LICN),
      1                 IKEEP(5*N), IW(8*N), IDISP(10), IFAIL
       DOUBLE PRECISION A(LICN), PIVOT, W(N)
       LOGICAL          LBLOCK, GROW, ABORT(4)
```

3. Description

Given a real sparse matrix A, this routine may be used to obtain the LU factorization of a permutation of A,

$$PAQ=LU$$

where P and Q are permutation matrices, L is unit lower triangular and U is upper triangular. The routine uses a sparse variant of Gaussian elimination, and the pivotal strategy is designed to compromise between maintaining sparsity and controlling loss of accuracy through round-off.

Optionally the routine first permutes the matrix into block lower triangular form and then only factorizes the diagonal blocks. For some matrices this gives a considerable saving in storage and execution time.

Extensive data checks are made; duplicated non-zeros can be accumulated.

The factorization is intended to be used by F04AXF to solve sparse systems of linear equations $Ax=b$ or $A^T x=b$. If several matrices of the same sparsity pattern are to be factorized, F01BSF should be used for the second and subsequent matrices.

The method is fully described by Duff [1].

```
4. References

[1]   Duff I S (1977) MA28 -- a set of Fortran subroutines for
      sparse unsymmetric linear equations. A.E.R.E. Report R.8730.
      HMSO.

5. Parameters

 1:  N -- INTEGER                                        Input
     On entry: n, the order of the matrix A. Constraint: N > 0.

 2:  NZ -- INTEGER                                       Input
     On entry: the number of non-zero elements in the matrix A.
     Constraint: NZ > 0.

 3:  A(LICN) -- DOUBLE PRECISION array             Input/Output
     On entry: A(i), for i = 1,2,...,NZ must contain the non-
     zero elements of the sparse matrix A. They can be in any
     order since the routine will reorder them. On exit: the non-
     zero elements in the LU factorization. The array must not be
     changed by the user between a call of this routine and a
     call of F04AXF.

 4:  LICN -- INTEGER                                     Input
     On entry:
     the dimension of the arrays A and ICN as declared in the
     (sub)program from which F01BRF is called.
     Since the factorization is returned in A and ICN, LICN
     should be large enough to accommodate this and should
     ordinarily be 2 to 4 times as large as NZ. Constraint: LICN
     >= NZ.

 5:  IRN(LIRN) -- INTEGER array                    Input/Output
     On entry: IRN(i), for i = 1,2,...,NZ must contain the row
     index of the non-zero element stored in A(i). On exit: the
     array is overwritten and is not needed for subsequent calls
     of F01BSF or F04AXF.

 6:  LIRN -- INTEGER                                     Input
     On entry:
     the dimension of the array IRN as declared in the
     (sub)program from which F01BRF is called.
     It need not be as large as LICN; normally it will not need
     to be very much greater than NZ. Constraint: LIRN >= NZ.

 7:  ICN(LICN) -- INTEGER array                    Input/Output
     On entry: ICN(i), for i = 1,2,...,NZ must contain the
     column index of the non-zero element stored in A(i). On
     exit: the column indices of the non-zero elements in the
     factorization. The array must not be changed by the user
     between a call of this routine and subsequent calls of
     F01BSF or F04AXF.

 8:  PIVOT -- DOUBLE PRECISION                              Input
     On entry: PIVOT should have a value in the range 0.0 <=
     PIVOT <= 0.9999 and is used to control the choice of pivots.
     If PIVOT < 0.0, the value 0.0 is assumed, and if PIVOT > 0.
     9999, the value 0.9999 is assumed. When searching a row for
     a pivot, any element is excluded which is less than PIVOT
     times the largest of those elements in the row available as
     pivots. Thus decreasing PIVOT biases the algorithm to
     maintaining sparsity at the expense of stability. Suggested
     value: PIVOT = 0.1 has been found to work well on test
     examples.

 9:  IKEEP(5*N) -- INTEGER array                           Output
     On exit: indexing information about the factorization. The
     array must not be changed by the user between a call of this
     routine and calls of F01BSF or F04AXF.

10:  IW(8*N) -- INTEGER array                           Workspace

11:  W(N) -- DOUBLE PRECISION array                        Output
     On exit: if GROW = .TRUE., W(1) contains an estimate (an
     upper bound) of the increase in size of elements encountered
     during the factorization (see GROW); the rest of the array
     is used as workspace.

     If GROW = .FALSE., the array is not used.

12:  LBLOCK -- LOGICAL                                      Input
     On entry: if LBLOCK = .TRUE., the matrix is pre-ordered
     into block lower triangular form before the LU factorization
     is performed; otherwise the entire matrix is factorized.
     Suggested value: LBLOCK = .TRUE. unless the matrix is known
     to be irreducible.

13:  GROW -- LOGICAL                                        Input
     On entry: if GROW = .TRUE., then on exit W(1) contains an
     estimate (an upper bound) of the increase in size of
     elements encountered during the factorization. If the matrix
     is well-scaled (see Section 8.2), then a high value for W(1)
     indicates that the LU factorization may be inaccurate and
     the user should be wary of the results and perhaps increase
     the parameter PIVOT for subsequent runs (see Section 7).
     Suggested value: GROW = .TRUE..

14:  ABORT(4) -- LOGICAL array                              Input
     On entry:
```

```
                if ABORT(1) = .TRUE., the routine will exit
                immediately on detecting a structural singularity (one
                that depends on the pattern of non-zeros) and return

                IFAIL = 1; otherwise it will complete the
                factorization (see Section 8.3).

                If ABORT(2) = .TRUE., the routine will exit
                immediately on detecting a numerical singularity (one
                that depends on the numerical values) and return IFAIL
                = 2; otherwise it will complete the factorization (see
                Section 8.3).

                If ABORT(3) = .TRUE., the routine will exit
                immediately (with IFAIL = 5) when the arrays A and ICN
                are filled up by the previously factorized, active and
                unfactorized parts of the matrix; otherwise it
                continues so that better guidance on necessary array
                sizes can be given in IDISP(6) and IDISP(7), and will
                exit with IFAIL in the range 4 to 6. Note that there
                is always an immediate error exit if the array IRN is
                too small.

                If ABORT(4) = .TRUE., the routine exits immediately
                (with IFAIL = 13) if it finds duplicate elements in
                the input matrix. If ABORT(4) = .FALSE., the routine
                proceeds using a value equal to the sum of the
                duplicate elements. In either case details of each
                duplicate element are output on the current advisory
                message unit (see X04ABF), unless suppressed by the
                value of IFAIL on entry.
            Suggested values:
                ABORT(1) = .TRUE.

                ABORT(2) = .TRUE.

                ABORT(3) = .FALSE.

                ABORT(4) = .TRUE..

       15:  IDISP(10) -- INTEGER array                           Output
            On exit: IDISP is used to communicate information about the
            factorization to the user and also between a call of F01BRF
            and subsequent calls to F01BSF or F04AXF.
                IDISP(1) and IDISP(2), indicate the position in arrays
                A and ICN of the first and last elements in the LU
                factorization of the diagonal blocks. (IDISP(2) gives
                the number of non-zeros in the factorization.)

                IDISP(3) and IDISP(4), monitor the adequacy of 'elbow
```

```
          room' in the arrays IRN and A/ICN respectively, by
          giving the number of times that the data in these
          arrays has been compressed during the factorization to
          release more storage. If either IDISP(3) or IDISP(4)
          is quite large (say greater than 10), it will probably
          pay the user to increase the size of the corresponding
          array(s) for subsequent runs. If either is very low or
          zero, then the user can perhaps save storage by
          reducing the size of the corresponding array(s).

          IDISP(5), gives an upper bound on the rank of the
          matrix.

          IDISP(6) and IDISP(7), give the minimum size of arrays
          IRN and A/ICN respectively which would enable a
          successful run on an identical matrix (but some '
          elbow-room' should be allowed - see Section 8).

          IDISP(8) to (10), are only used if LBLOCK = .TRUE..

          IDISP(8), gives the structural rank of the matrix.

          IDISP(9), gives the number of diagonal blocks.

          IDISP(10), gives the size of the largest diagonal
          block.

          IDISP(1) and IDISP(2), must not be changed by the user
          between a call of F01BRF and subsequent calls to
          F01BSF or F04AXF.

 16:  IFAIL -- INTEGER                                Input/Output
      For this routine, the normal use of IFAIL is extended to
      control the printing of error and warning messages as well
      as specifying hard or soft failure (see the Essential
      Introduction).

      Before entry, IFAIL must be set to a value with the decimal
      expansion cba, where each of the decimal digits c, b and a
      must have a value of 0 or 1.
      a=0   specifies hard failure, otherwise soft failure;

      b=0   suppresses error messages, otherwise error messages
            will be printed (see Section 6);

      c=0   suppresses warning messages, otherwise warning
            messages will be printed (see Section 6).
      The recommended value for inexperienced users is 110 (i.e.,
      hard failure with all messages printed).
```

```
     Unless the routine detects an error (see Section 6), IFAIL
     contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

For each error, an explanatory error message is output on the
current error message unit (as defined by X04AAF), unless
suppressed by the value of IFAIL on entry.

IFAIL=-2
     Successful factorization of a numerically singular matrix
     (which may also be structurally singular) (see Section 8.3).

IFAIL=-1
     Successful factorization of a structurally singular matrix
     (see Section 8.3).

IFAIL= 1
     The matrix is structurally singular and the factorization
     has been abandoned (ABORT(1) was .TRUE. on entry).

IFAIL= 2
     The matrix is numerically singular and the factorization has
     been abandoned (ABORT(2) was .TRUE. on entry).

IFAIL= 3
     LIRN is too small: there is not enough space in the array
     IRN to continue the factorization. The user is recommended
     to try again with LIRN (and the length of IRN) equal to at
     least IDISP(6) + N/2.

IFAIL= 4
     LICN is much too small: there is much too little space in
     the arrays A and ICN to continue the factorization.

IFAIL= 5
     LICN is too small: there is not enough space in the arrays A
     and ICN to store the factorization. If ABORT(3) was .FALSE.
     on entry, the factorization has been completed but some of
     the LU factors have been discarded to create space, IDISP(7)
     then gives the minimum value of LICN (i.e., the minimum
     length of A and ICN) required for a successful factorization
     of the same matrix.

IFAIL= 6
     LICN and LIRN are both too small: effectively this is a
     combination of IFAIL = 3 and IFAIL = 5 (with ABORT(3) = .
     FALSE.).
```

IFAIL= 7
     LICN is too small: there is not enough space in the arrays A
     and ICN for the permutation to block triangular form.

IFAIL= 8
     On entry N <= 0.

IFAIL= 9
     On entry NZ <= 0.

IFAIL= 10
     On entry LICN < NZ.

IFAIL= 11
     On entry LIRN < NZ.

IFAIL= 12
     On entry an element of the input matrix has a row or column
     index (i.e., an element of IRN or ICN) outside the range 1
     to N.

IFAIL= 13
     Duplicate elements have been found in the input matrix and
     the factorization has been abandoned (ABORT(4) = .TRUE. on
     entry).

7. Accuracy

The factorization obtained is exact for a perturbed matrix whose (i,j)th element differs from a_{ij} by less than 3(epsilon)(rho)m_{ij} where (epsilon) is the machine precision, (rho) is the growth value returned in W(1) if GROW = .TRUE., and m_{ij} the number of Gaussian elimination operations applied to element (i,j). The value of m_{ij} is not greater than n and is usually much less. Small (rho) values therefore guarantee accurate results, but unfortunately large (rho) values may give a very pessimistic indication of accuracy.

8. Further Comments

8.1. Timing

The time required may be estimated very roughly from the number (tau) of non-zeros in the factorized form (output as IDISP(2)) and for this routine and its associates is

F01BRF: $5(tau)^2/n$ units

F01BSF: $(tau)^2/n$ units

F04AXF: $2(tau)$ units

where our unit is the time for the inner loop of a full matrix code (e.g. solving a full set of equations takes about $\frac{1}{3}n^3$ units). Note that the faster F01BSF time makes it well worthwhile to use this for a sequence of problems with the same pattern.

It should be appreciated that (tau) varies widely from problem to problem. For network problems it may be little greater than NZ, the number of non-zeros in A; for discretisation of 2-dimensional and 3-dimensional partial differential equations it may be about $3n\log_2 n$ and $\frac{1}{2}n^{5/3}$, respectively.

The time taken to find the block lower triangular form (LBLOCK = it is not found (LBLOCK = .FALSE.). If the matrix is irreducible (IDISP(9) = 1 after a call with LBLOCK = .TRUE.) then this time is wasted. Otherwise, particularly if the largest block is small (IDISP(10)<<n), the consequent savings are likely to be greater.

The time taken to estimate growth (GROW = .TRUE.) is typically under 2% of the overall time.

The overall time may be substantially increased if there is inadequate 'elbow-room' in the arrays A, IRN and ICN. When the sizes of the arrays are minimal (IDISP(6) and IDISP(7)) it can execute as much as three times slower. Values of IDISP(3) and IDISP(4) greater than about 10 indicate that it may be worthwhile to increase array sizes.

8.2. Scaling

The use of a relative pivot tolerance PIVOT essentially presupposes that the matrix is well-scaled, i.e., that the matrix elements are broadly comparable in size. Practical problems are often naturally well-scaled but particular care is needed for problems containing mixed types of variables (for example millimetres and neutron fluxes).

8.3. Singular and Rectangular Systems

```
          It is envisaged that this routine will almost always be called
          for square non-singular matrices and that singularity indicates
          an error condition. However, even if the matrix is singular it is
          possible to complete the factorization. It is even possible for
          F04AXF to solve a set of equations whose matrix is singular
          provided the set is consistent.

          Two forms of singularity are possible. If the matrix would be
          singular for any values of the non-zeros (e.g. if it has a whole
          row of zeros), then we say it is structurally singular, and
          continue only if ABORT(1) = .FALSE.. If the matrix is non-
          singular by virtue of the particular values of the non-zeros,
          then we say that it is numerically singular and continue only if
          ABORT(2) = .FALSE..

          Rectangular matrices may be treated by setting N to the larger of
          the number of rows and numbers of columns and setting ABORT(1) =

          Note: the soft failure option should be used (last digit of IFAIL
          = 1) if the user wishes to factorize singular matrices with ABORT
          (1) or ABORT(2) set to .FALSE..

          8.4. Duplicated Non-zeros

          The matrix A may consist of a sum of contributions from different
          sub-systems (for example finite elements). In such cases the user
          may rely on this routine to perform assembly, since duplicated
          elements are summed.

          9. Example

          To factorize the real sparse matrix:

                                 ( 5  0  0  0 0  0)
                                 ( 0  2 -1  2 0  0)
                                 ( 0  0  3  0 0  0)
                                 (-2  0  0  1 1  0).
                                 (-1  0  0 -1 2 -3)
                                 (-1 -1  0  0 0  6)

          This example program simply prints out some information about the
          factorization as returned by F01BRF in W(1) and IDISP. Normally
          the call of F01BRF would be followed by a call of F04AXF (see
          Example for F04AXF).

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

———-

16.5.4 Factorizes a real sparse matrix

— nagf.ht —

```
\begin{page}{manpageXXf01bsf}{NAG Documentation: f01bsf}
\beginscroll
\begin{verbatim}

     F01BSF(3NAG)      Foundation Library (12/10/92)      F01BSF(3NAG)

          F01 -- Matrix Factorizations                              F01BSF
                  F01BSF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F01BSF factorizes a real sparse matrix using the pivotal sequence
          previously obtained by F01BRF when a matrix of the same sparsity
          pattern was factorized.

          2. Specification

                 SUBROUTINE F01BSF (N, NZ, A, LICN, IVECT, JVECT, ICN,
                1                   IKEEP, IW, W, GROW, ETA, RPMIN, ABORT,
                2                   IDISP, IFAIL)
                 INTEGER          N, NZ, LICN, IVECT(NZ), JVECT(NZ), ICN
                1                 (LICN), IKEEP(5*N), IW(8*N), IDISP(2),
                2                 IFAIL
                 DOUBLE PRECISION A(LICN), W(N), ETA, RPMIN
                 LOGICAL          GROW, ABORT

          3. Description

          This routine accepts as input a real sparse matrix of the same
```

sparsity pattern as a matrix previously factorized by a call of F01BRF. It first applies to the matrix the same permutations as were used by F01BRF, both for permutation to block triangular form and for pivoting, and then performs Gaussian elimination to obtain the LU factorization of the diagonal blocks.

Extensive data checks are made; duplicated non-zeros can be accumulated.

The factorization is intended to be used by F04AXF to solve sparse systems of linear equations Ax=b or $A^T x=b$.

F01BSF is much faster than F01BRF and in some applications it is expected that there will be many calls of F01BSF for each call of F01BRF.

The method is fully described in Duff [1].

4. References

[1] Duff I S (1977) MA28 -- a set of Fortran subroutines for sparse unsymmetric linear equations. A.E.R.E. Report R.8730. HMSO.

5. Parameters

```
 1:  N -- INTEGER                                          Input
     On entry: n, the order of the matrix A. Constraint: N > 0.

 2:  NZ -- INTEGER                                         Input
     On entry: the number of non-zeros in the matrix A.
     Constraint: NZ > 0.

 3:  A(LICN) -- DOUBLE PRECISION array              Input/Output
     On entry: A(i), for i = 1,2,...,NZ must contain the non-
     zero elements of the sparse matrix A. They can be in any
     order since the routine will reorder them. On exit: the non-
     zero elements in the factorization. The array must not be
     changed by the user between a call of this routine and a
     call of F04AXF.

 4:  LICN -- INTEGER                                       Input
     On entry:
     the dimension of the arrays A and ICN as declared in the
     (sub)program from which F01BSF is called.
     It should have the same value as it had for F01BRF.
     Constraint: LICN >= NZ.

 5:  IVECT(NZ) -- INTEGER array                            Input
 6:  JVECT(NZ) -- INTEGER array                          Input
     On entry: IVECT(i) and JVECT(i), for i = 1,2,...,NZ must
     contain the row index and the column index respectively of
     the non-zero element stored in A(i).

 7:  ICN(LICN) -- INTEGER array                          Input
     On entry: the same information as output by F01BRF. It must
     not be changed by the user between a call of this routine
     and a call of F04AXF.

 8:  IKEEP(5*N) -- INTEGER array                         Input
     On entry: the same indexing information about the
     factorization as output from F01BRF. It must not be changed
     between a call of this routine and a call of F04AXF.

 9:  IW(8*N) -- INTEGER array                        Workspace

10:  W(N) -- DOUBLE PRECISION array                     Output
     On exit: if GROW = .TRUE., W(1) contains an estimate (an
     upper bound) of the increase in size of elements encountered
     during the factorization (see GROW); the rest of the array
     is used as workspace.

     If GROW = .FALSE., the array is not used.

11:  GROW -- LOGICAL                                     Input
     On entry: if GROW = .TRUE., then on exit W(1) contains an
     estimate (an upper bound) of the increase in size of
     elements encountered during the factorization. If the matrix
     is well-scaled (see Section 8.2), then a high value for W(1)
     indicates that the LU factorization may be inaccurate and
     the user should be wary of the results and perhaps increase
     the parameter PIVOT for subsequent runs (see Section 7).

12:  ETA -- DOUBLE PRECISION                             Input
     On entry: the relative pivot threshold below which an error
     diagnostic is provoked and IFAIL is set to 7. If ETA is
     greater than 1.0, then no check on pivot size is made.
                                 -4
     Suggested value: ETA = 10  .

13:  RPMIN -- DOUBLE PRECISION                          Output
     On exit: if ETA is less than 1.0, then RPMIN gives the
     smallest ratio of the pivot to the largest element in the
     row of the corresponding upper triangular factor thus
     monitoring the stability of the factorization. If RPMIN is
     very small it may be advisable to perform a new
     factorization using F01BRF.
```

```
14:  ABORT -- LOGICAL                                       Input
     On entry: if ABORT = .TRUE., the routine exits immediately
     (with IFAIL = 8) if it finds duplicate elements in the input
     matrix. If ABORT = .FALSE., the routine proceeds using a
     value equal to the sum of the duplicate elements. In either
     case details of each duplicate element are output on the
     current advisory message unit (see X04ABF), unless
     suppressed by the value of IFAIL on entry. Suggested value:
     ABORT = .TRUE..

15:  IDISP(2) -- INTEGER array                              Input
     On entry: IDISP(1) and IDISP(2) must be unchanged since the
     previous call of F01BRF.

16:  IFAIL -- INTEGER                                Input/Output
     For this routine, the normal use of IFAIL is extended to
     control the printing of error and warning messages as well
     as specifying hard or soft failure (see the Essential
     Introduction).

     Before entry, IFAIL must be set to a value with the decimal
     expansion cba, where each of the decimal digits c, b and a
     must have a value of 0 or 1.
     a=0   specifies hard failure, otherwise soft failure;

     b=0   suppresses error messages, otherwise error messages
           will be printed (see Section 6);

     c=0   suppresses warning messages, otherwise warning
           messages will be printed (see Section 6).
     The recommended value for inexperienced users is 110 (i.e.,
     hard failure with all messages printed).

     Unless the routine detects an error (see Section 6), IFAIL
     contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

For each error, an explanatory error message is output on the
current error message unit (as defined by X04AAF), unless
suppressed by the value of IFAIL on entry.

IFAIL= 1
     On entry N <= 0.

IFAIL= 2
     On entry NZ <= 0.
```

IFAIL= 3
    On entry LICN < NZ.

IFAIL= 4
    On entry an element of the input matrix has a row or column index (i.e., an element of IVECT or JVECT) outside the range 1 to N.

IFAIL= 5
    The input matrix is incompatible with the matrix factorized by the previous call of F01BRF (see Section 8).

IFAIL= 6
    The input matrix is numerically singular.

IFAIL= 7
    A very small pivot has been detected (see Section 5, ETA). The factorization has been completed but is potentially unstable.

IFAIL= 8
    Duplicate elements have been found in the input matrix and the factorization has been abandoned (ABORT = .TRUE. on entry).

7. Accuracy

The factorization obtained is exact for a perturbed matrix whose (i,j)th element differs from a_{ij} by less than 3(epsilon)(rho)m_{ij} where (epsilon) is the machine precision, (rho) is the growth value returned in W(1) if GROW = .TRUE., and m_{ij} the number of Gaussian elimination operations applied to element (i,j).

If (rho) = W(1) is very large or RPMIN is very small, then a fresh call of F01BRF is recommended.

8. Further Comments

If the user has a sequence of problems with the same sparsity pattern then this routine is recommended after F01BRF has been called for one such problem. It is typically 4 to 7 times faster but is potentially unstable since the previous pivotal sequence is used. Further details on timing are given in document F01BRF.

If growth estimation is performed (GROW = .TRUE.), then the time increases by between 5% and 10%. Pivot size monitoring (ETA <= 1. 0) involves a similar overhead.

```
          We normally expect this routine to be entered with a matrix
          having the same pattern of non-zeros as was earlier presented to
          F01BRF. However there is no record of this pattern, but rather a
          record of the pattern including all fill-ins. Therefore we permit
          additional non-zeros in positions corresponding to fill-ins.

          If singular matrices are being treated then it is also required
          that the present matrix be sufficiently like the previous one for
          the same permutations to be suitable for factorization with the
          same set of zero pivots.

          9. Example

          To factorize the real sparse matrices

                                 ( 5  0  0  0 0  0)
                                 ( 0  2 -1  2 0  0)
                                 ( 0  0  3  0 0  0)
                                 (-2  0  0  1 1  0)
                                 (-1  0  0 -1 2 -3)
                                 (-1 -1  0  0 0  6)

          and

                                (10  0  0  0  0  0)
                                ( 0 12 -3 -1  0  0)
                                ( 0  0 15  0  0  0)
                                (-2  0  0 10 -1  0).
                                (-1  0  0 -5  1 -1)
                                (-1 -2  0  0  0  6)

          This example program simply prints the values of W(1) and RPMIN
          returned by F01BSF. Normally the calls of F01BRF and F01BSF would
          be followed by calls of F04AXF.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

```

16.5.5 Incomplete Cholesky factorization

— nagf.ht —

```
\begin{page}{manpageXXf01maf}{NAG Documentation: f01maf}
\beginscroll
\begin{verbatim}

     F01MAF(3NAG)      Foundation Library (12/10/92)      F01MAF(3NAG)

          F01 -- Matrix Factorizations                              F01MAF
                  F01MAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F01MAF computes an incomplete Cholesky factorization of a real
          sparse symmetric positive-definite matrix A.

          2. Specification

                 SUBROUTINE F01MAF (N, NZ, A, LICN, IRN, LIRN, ICN, DROPTL,
                1                   DENSW, WKEEP, IKEEP, IWORK, ABORT,
                2                   INFORM, IFAIL)
                 INTEGER          N, NZ, LICN, IRN(LIRN), LIRN, ICN(LICN),
                1                 IKEEP(2*N), IWORK(6*N), INFORM(4), IFAIL
                 DOUBLE PRECISION A(LICN), DROPTL, DENSW, WKEEP(3*N)
                 LOGICAL          ABORT(3)

          3. Description

          F01MAF computes an incomplete Cholesky factorization

                                        T T
                                  C=PLDL P ,   WAW=C+E

          for the sparse symmetric positive-definite matrix A, where P is a
          permutation matrix, L is a unit lower triangular matrix, D is a
          diagonal matrix with positive diagonal elements, E is an error
          matrix representing elements dropped during the factorization and
          diagonal elements that have been modified to ensure that C is
```

positive-definite, and W is a diagonal matrix, chosen to make the diagonal elements of WAW unity.

$W^{-1}CW^{-1}$ is a pre-conditioning matrix for A, and the factorization of C is intended to be used by F04MAF to solve systems of linear equations Ax=b.

The permutation matrix P is chosen to reduce the amount of fill-in that occurs in L and the user-supplied parameter DROPTL can also be used to control the amount of fill-in that occurs.

Full details on the factorization can be found in Munksgaard [1].

F01MAF is based on the Harwell Library routine MA31A.

4. References

[1] Munksgaard N (1980) Solving Sparse Symmetric Sets of Linear Equations by Pre-conditioned Conjugate Gradients. ACM Trans. Math. Softw. 6 206--219.

5. Parameters

1: N -- INTEGER Input
On entry: n, the order of the matrix A. Constraint: N >= 1.

2: NZ -- INTEGER Input
On entry: the number of non-zero elements in the upper triangular part of the matrix A, including the number of elements on the leading diagonal. Constraint: NZ >= N.

3: A(LICN) -- DOUBLE PRECISION array Input/Output
On entry: the first NZ elements of the array A must contain the non-zero elements of the upper triangular part of the sparse positive-definite symmetric matrix A, including the elements on the leading diagonal. On exit: the first (NZ-N) elements of A contain the elements above the diagonal of the matrix WAW, where W is a diagonal matrix whose ith diagonal element is $w_i=a_{ii}^{-1/2}$. These elements are returned in order by rows and the value returned in ICN(k) gives the column index of the element returned in A(k). The value w_i is returned in the ith element of the array WKEEP. The remaining LROW-NZ+N elements of A, where LROW is the value returned in INFORM(1), return details of the factorization for use by F04MAF.

4: LICN -- INTEGER Input

On entry:
the dimension of the array A as declared in the (sub)program from which F01MAF is called.
If fill-in is expected during the factorization, then a larger value of LICN will allow fewer elements to be dropped during the factorization, thus giving a more accurate factorization, which in turn will almost certainly mean that fewer iterations will be required by F04MAF. Constraint: LICN>=2*NZ.

5: IRN(LIRN) -- INTEGER array Input/Output
On entry: IRN(k), for k = 1,2,...,NZ must contain the row index of the non-zero element of the matrix A supplied in A (k). On exit: the first LCOL elements of IRN, where LCOL is the value returned in INFORM(2), return details of the factorization for use by F04MAF.

6: LIRN -- INTEGER Input
On entry:
the dimension of the array IRN as declared in the (sub)program from which F01MAF is called.
LIRN must be at least NZ, but, as with LICN, if fill-in is expected then a larger value of LIRN will allow a more accurate factorization. For this purpose LIRN should exceed NZ by the same amount that LICN exceeds 2*NZ. Constraint: LIRN >= NZ.

7: ICN(LICN) -- INTEGER array Input/Output
On entry: ICN(k), for k = 1,2,...,NZ must contain the column index of the non-zero element of the matrix A supplied in A (k). Thus a_{ij} =A(k), where i = IRN(k) and j = ICN(k). On exit: the first (NZ-N) elements of ICN give the column indices of the first (NZ-N) elements returned in A. The remaining LROW - NZ + N elements of ICN return details of the factorization for use by F04MAF.

8: DROPTL -- DOUBLE PRECISION Input/Output
On entry: a value in the range [-1.0,1.0] to be used as a tolerance in deciding whether or not to drop elements during the factorization. At the kth pivot step the element $a_{ij}^{(k+1)}$ is dropped if it would cause fill-in and if

$$|a_{ij}^{(k+1)}|<|DROPTL|*\sqrt{a_{ii}^{(k)}a_{jj}^{(k)}}.$$

If DROPTL is supplied as negative, then it is not altered

```
     during the factorization and so is unchanged on exit, but if
     DROPTL is supplied as positive then it may be altered by the
     routine with the aim of obtaining an accurate factorization
     in the space available. If DROPTL is supplied as -1.0, then
     no fill-in will occur during the factorization; and if
     DROPTL is supplied as 0.0 then a complete factorization is
     performed. On exit: may be overwritten with the value used
     by the routine in order to obtain an accurate factorization
     in the space available, if DROPTL > 0.0 on entry.

 9:  DENSW -- DOUBLE PRECISION                       Input/Output
     On entry: a value in the range [0.0,1.0] to be used in
     deciding whether or not to regard the active part of the
     matrix at the kth pivot step as being full. If the ratio of
     non-zero elements to the total number of elements is greater
     than or equal to DENSW, then the active part is regarded as
     full. If DENSW < 1.0, then the storage used is likely to
     increase compared to the case where DENSW = 0, but the
     execution time is likely to decrease. Suggested value: DENSW
     = 0.8. On exit: if on entry DENSW is not in the range
     [0.0,1.0], then it is set to 0.8. Otherwise it is unchanged.

10:  WKEEP(3*N) -- DOUBLE PRECISION array                  Output
     On exit: information which must be passed unchanged to
     F04MAF. The first N elements contain the values w , for
                                                      i
     i=1,2,...,n, and the next N elements contain the diagonal
     elements of D.

11:  IKEEP(2*N) -- INTEGER array                           Output
     On exit: information which must be passed unchanged to
     F04MAF.

12:  IWORK(6*N) -- INTEGER array                        Workspace

13:  ABORT(3) -- LOGICAL array                              Input
     On entry:
          if ABORT(1) = .TRUE., the routine will exit
          immediately on detecting duplicate elements and return
          IFAIL = 5. Otherwise when ABORT(1) = .FALSE., the
          calculations will continue using the sum of the
          duplicate entries. In either case details of the
          duplicate elements are output on the current advisory
          message unit (see X04ABF), unless suppressed by the
          value of IFAIL on entry.

          If ABORT(2) = .TRUE., the routine will exit
          immediately on detecting a zero or negative pivot
          element and return IFAIL = 6. Otherwise when ABORT(2)
          = .FALSE., the zero or negative pivot element will be
```

```
                modified to ensure positive-definiteness and a message
                will be printed on the current advisory message unit,
                unless suppressed by the value of IFAIL on entry.

                If ABORT(3) = .TRUE., the routine will exit
                immediately if the arrays A and ICN have been filled
                up and return IFAIL = 7. Otherwise when ABORT(3) = .
                FALSE., the data in the arrays is compressed to
                release more storage and a message will be printed on
                the current advisory message unit, unless suppressed
                by the value of IFAIL on entry. If DROPTL is positive
                on entry, it may be modified in order to allow a
                factorization to be completed in the available space.
           Suggested values:
                ABORT(1) = .TRUE.,

                ABORT(2) = .TRUE.,

                ABORT(3) = .TRUE..

      14:  INFORM(4) -- INTEGER array                             Output
           On exit:
                INFORM(1) returns the number of elements of A and ICN
                that have been used by the routine. Thus at least the
                first INFORM(1) elements of A and of ICN must be
                supplied to F04MAF.

                Similarly, INFORM(2) returns the number of elements of
                IRN that have been used by the routine and so at least
                the first INFORM(2) elements must be supplied to
                F04MAF.

                INFORM(3) returns the number of entries supplied in A
                that corresponded to diagonal and duplicate elements.
                If no duplicate entries were found, then INFORM(3)
                will return the value of N.

                INFORM(4) returns the value k of the pivot step from
                which the active matrix was regarded as full.
           INFORM must be passed unchanged to F04MAF.

      15:  IFAIL -- INTEGER                                 Input/Output
           For this routine, the normal use of IFAIL is extended to
           control the printing of error and warning messages as well
           as specifying hard or soft failure (see the Essential
           Introduction).

           Before entry, IFAIL must be set to a value with the decimal
           expansion cba, where each of the decimal digits c, b and a
           must have a value of 0 or 1.
```

```
     a=0   specifies hard failure, otherwise soft failure;

     b=0   suppresses error messages, otherwise error messages
           will be printed (see Section 6);

     c=0   suppresses warning messages, otherwise warning
           messages will be printed (see Section 6).
     The recommended value for inexperienced users is 110 (i.e.,
     hard failure with all messages printed).

     Unless the routine detects an error (see Section 6), IFAIL
     contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

For each error, an explanatory error message is output on the
current error message unit (as defined by X04AAF), unless
suppressed by the value of IFAIL on entry.

IFAIL= 1
     On entry N < 1,

     or       NZ < N,

     or       LIRN < NZ,

     or       LICN<2*NZ.

IFAIL= 2
     One of the conditions 0 < IRN(k) <= ICN(k) <= N is not
     satisfied so that A(k) is not in the upper triangle of the
     matrix. No further computation is attempted.

IFAIL= 3
     One of the diagonal elements of the matrix A is zero or
     negative so that A is not positive-definite. No further
     computation is attempted.

IFAIL= 4
     The available space has been used and no further
     compressions are possible. The user should either increase
     DROPTL, or allocate more space to A, IRN and ICN.

     For all the remaining values of IFAIL the computations will
     continue in the case of soft failure, so that more than one
     advisory message may be printed.

IFAIL= 5
```

```
     Duplicate elements have been detected and ABORT(1) = .TRUE..

IFAIL= 6
     A zero or negative pivot element has been detected during
     the factorization and ABORT(2) = .TRUE..

     This should not happen if A is an M-matrix (see Munksgaard
     [1]), but may occur for other types of positive-definite
     matrix.

IFAIL= 7
     The available space has been used and ABORT(3) = .TRUE..

7. Accuracy

The accuracy of the factorization will be determined by the size
of the elements that are dropped and the size of the
modifications made to the diagonal elements. If these sizes are
small then the computed factors will correspond to a matrix close
to A and the number of iterations required by F04MAF will be
small. The more incomplete the factorization, the higher the
number of iterations required by F04MAF.

8. Further Comments

The time taken by the routine will depend upon the sparsity
pattern of the matrix and the number of fill-ins that occur
during the factorization. At the very least the time taken can be
expected to be roughly proportional to n(tau), where (tau) is the
number of non-zeros.
The routine is intended for use with positive-definite matrices,
but the user is warned that it will not necessarily detect non-
positive-definiteness. Indeed the routine may return a
factorization that can satisfactorily be used by F04MAF even when
A is not positive-definite, but this should not be relied upon as
F04MAF may not converge.

9. Example

The example program illustrates the use of F01MAF in conjunction
with F04MAF to solve the 16 linear equations Ax=b, where

                (1 z     z                    )
                (z 1 z     z                  )
                (  z 1 z     z                )
                (    z 1 0     z              )
                (z     0 1 z     z            )
                (  z     z 1 z     z          )
                (    z     z 1 z     z        )
                (      z     z 1 0     z      )
```

```
                 A=(        z     0 1 z     z      ).
                   (         z     z 1 z     z    )
                   (          z     z 1 z     z  )
                   (           z     z 1 0     z)
                   (            z     0 1 z    )
                   (             z     z 1 z  )
                   (              z     z 1 z)
                   (               z     z 1)

        T ( 1  1  1  1  1     1  1     1  1  1  1  1)
       b =( -  -  -  -  - 0 0  -  - 0 0  -  -  -  -  -),
          ( 2  4  4  2  4     4  4     4  2  4  4  2)

                 1
       where z=- -.
                 4

       The n by n matrix A arises in the solution of Laplace's equation
       in a unit square, using a 5-point formula with a 6 by 6
       discretisation, with unity on the boundaries.

       The drop tolerance, DROPTL, is taken as 0.1, and the density
       factor, DENSW, is taken as 0.8. The value IFAIL = 111 is used so
       that advisory and error messages will be printed, but soft
       failure would occur if IFAIL were returned as non-zero.

       A relative accuracy of about 0.0001 is requested in the solution
       from F04MAF, with a maximum of 50 iterations.

       The example program for F02FJF illustrates the use of F01MAF and
       F04MAF in solving an eigenvalue problem.

       The example program is not reproduced here. The source code for
       all example programs is distributed with the NAG Foundation
       Library software and should be available on-line.

     F01MCF(3NAG)      Foundation Library (12/10/92)      F01MCF(3NAG)

          F01 -- Matrix Factorizations                               F01MCF
                  F01MCF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F01MCF computes the Cholesky factorization of a real symmetric
          positive-definite variable-bandwidth matrix.

          2. Specification

                 SUBROUTINE F01MCF (N, A, LAL, NROW, AL, D, IFAIL)
                 INTEGER          N, LAL, NROW(N), IFAIL
                 DOUBLE PRECISION A(LAL), AL(LAL), D(N)

          3. Description

          This routine determines the unit lower triangular matrix L and
                                                                   T
          the diagonal matrix D in the Cholesky factorization A=LDL  of a
          symmetric positive-definite variable-bandwidth matrix A of order
          n. (Such a matrix is sometimes called a 'sky-line' matrix.)

          The matrix A is represented by the elements lying within the
          envelope of its lower triangular part, that is, between the first
          non-zero of each row and the diagonal (see Section 9 for an
          example). The width NROW(i) of the ith row is the number of
          elements between the first non-zero element and the element on
          the diagonal, inclusive. Although, of course, any matrix
          possesses an envelope as defined, this routine is primarily
          intended for the factorization of symmetric positive-definite
          matrices with an average bandwidth which is small compared with n
          (also see Section 8).

          The method is based on the property that during Cholesky
          factorization there is no fill-in outside the envelope.
```

The determination of L and D is normally the first of two steps in the solution of the system of equations Ax=b. The remaining step, viz. the solution of $LDL^T x=b$ may be carried out using F04MCF.

[2] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

1: N -- INTEGER Input
On entry: n, the order of the matrix A. Constraint: N >= 1.

2: A(LAL) -- DOUBLE PRECISION array Input
On entry: the elements within the envelope of the lower triangle of the positive-definite symmetric matrix A, taken in row by row order. The following code assigns the matrix elements within the envelope to the correct elements of the array:

```
K = 0
DO 20 I = 1, N
DO 10 J = I-NROW(I)+1, I
K = K + 1
A(K) = matrix (I,J)
10    CONTINUE
20 CONTINUE
```

See also Section 8.

3: LAL -- INTEGER Input
On entry: the smaller of the dimensions of the arrays A and AL as declared in the calling (sub)program from which F01MCF is called. Constraint: LAL >= NROW(1) + NROW(2) +... + NROW(n).

4: NROW(N) -- INTEGER array Input
On entry: NROW(i) must contain the width of row i of the matrix A, i.e., the number of elements between the first (leftmost) non-zero element and the element on the diagonal, inclusive. Constraint: 1 <= NROW(i) <= i, for i=1,2,...,n.

5: AL(LAL) -- DOUBLE PRECISION array Output

```
     On exit: the elements within the envelope of the lower
     triangular matrix L, taken in row by row order. The envelope
     of L is identical to that of the lower triangle of A. The
     unit diagonal elements of L are stored explicitly. See also
     Section 8.

 6:  D(N) -- DOUBLE PRECISION array                        Output
     On exit: the diagonal elements of the the diagonal matrix D
     . Note that the determinant of A is equal to the product of
     these diagonal elements. If the value of the determinant is
     required it should not be determined by forming the product
     explicitly, because of the possibility of overflow or
     underflow. The logarithm of the determinant may safely be
     formed from the sum of the logarithms of the diagonal
     elements.

 7:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     On entry N < 1,

     or       for some i, NROW(i) < 1 or NROW(i) > i,

     or       LAL < NROW(1) + NROW(2) +... + NROW(N).

IFAIL= 2
     A is not positive-definite, or this property has been
     destroyed by rounding errors. The factorization has not been
     completed.

IFAIL= 3
     A is not positive-definite, or this property has been
     destroyed by rounding errors. The factorization has been
     completed but may be very inaccurate (see Section 7).

7. Accuracy

If IFAIL = 0 on exit, then the computed L and D satisfy the
            T
relation LDL =A+F, where
```

$$||F||_2 <= km^2 (\epsilon) \max_i a_{ii}$$

and

$$||F||_2 <= km^2 (\epsilon) ||A||_2 ,$$

where k is a constant of order unity, m is the largest value of NROW(i), and (epsilon) is the machine precision. See Wilkinson and Reinsch [2], pp 25--27, 54--55. If IFAIL = 3 on exit, then the factorization has been completed although the matrix was not positive-definite. However the factorization may be very inaccurate and should be used only with great caution. For instance, if it is used to solve a set of equations Ax=b using F04MCF, the residual vector b-Ax should be checked.

8. Further Comments

The time taken by the routine is approximately proportional to the sum of squares of the values of NROW(i).

The distribution of row widths may be very non-uniform without undue loss of efficiency. Moreover, the routine has been designed to be as competitive as possible in speed with routines designed for full or uniformly banded matrices, when applied to such matrices.

Unless otherwise stated in the Users' Note for your implementation, the routine may be called with the same actual array supplied for parameters A and AL, in which case L overwrites the lower triangle of A. However this is not standard Fortran 77 and may not work in all implementations.

9. Example

To obtain the Cholesky factorization of the symmetric matrix, whose lower triangle is:

$$\begin{pmatrix} 1 & & & & & \\ 2 & 5 & & & & \\ 0 & 3 & 13 & & & \\ 0 & 0 & 0 & 16 & & \\ 5 & 14 & 18 & 8 & 55 & \\ 0 & 0 & 0 & 24 & 17 & 77 \end{pmatrix}.$$

For this matrix, the elements of NROW must be set to 1, 2, 2, 1,

```
          5, 3, and the elements within the envelope must be supplied in
          row order as:

          1, 2, 5, 3, 13, 16, 5, 14, 18, 8, 55, 24, 17, 77.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation

16.5.7 QR factorization of the real m by n matrix A

— nagf.ht —

```
\begin{page}{manpageXXf01qcf}{NAG Documentation: f01qcf}
\beginscroll
\begin{verbatim}

     F01QCF(3NAG)      Foundation Library (12/10/92)      F01QCF(3NAG)

          F01 -- Matrix Factorizations                             F01QCF
                  F01QCF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F01QCF finds the QR factorization of the real m by n matrix A,
          where m>=n.

          2. Specification

                 SUBROUTINE F01QCF (M, N, A, LDA, ZETA, IFAIL)
                 INTEGER          M, N, LDA, IFAIL
```

```
       DOUBLE PRECISION A(LDA,*), ZETA(*)
```

3. Description

The m by n matrix A is factorized as

$$A=Q\begin{pmatrix}R\\0\end{pmatrix} \qquad \text{when } m>n,$$

$$A=QR \qquad \text{when } m=n,$$

where Q is an m by m orthogonal matrix and R is an n by n upper triangular matrix. The factorization is obtained by Householder's method. The kth transformation matrix, Q_k, which is used to introduce zeros into the kth column of A is given in the form

$$Q_k=\begin{pmatrix}I & 0\\0 & T_k\end{pmatrix}$$

where

$$T_k=I-u_k u_k^T,$$

$$u_k=\begin{pmatrix}(zeta)_k\\z_k\end{pmatrix},$$

$(zeta)_k$ is a scalar and z_k is an (m-k) element vector. $(zeta)_k$ and z_k are chosen to annihilate the elements below the triangular part of A.

The vector u_k is returned in the kth element of the array ZETA and in the kth column of A, such that $(zeta)_k$ is in ZETA(k) and the elements of z_k are in A(k+1,k),...,A(m,k). The elements of R are returned in the upper triangular part of A.

Q is given by

$$Q=(Q\,Q\,\ldots Q)^T.$$

```
                         n n-1    1
```

Good background descriptions to the QR factorization are given in Dongarra et al [1] and Golub and Van Loan [2], but note that this routine is not based upon LINPACK routine DQRDC.

4. References

[3] Wilkinson J H (1965) The Algebraic Eigenvalue Problem. Oxford University Press.

5. Parameters

```
 1:  M -- INTEGER                                          Input
     On entry: m, the number of rows of A. Constraint: M >= N.

 2:  N -- INTEGER                                          Input
     On entry: n, the number of columns of A.

     When N = 0 then an immediate return is effected.
     Constraint: N >= 0.

 3:  A(LDA,*) -- DOUBLE PRECISION array             Input/Output
     Note: the second dimension of the array A must be at least
     max(1,n).
     On entry: the leading m by n part of the array A must
     contain the matrix to be factorized. On exit: the n by n
     upper triangular part of A will contain the upper triangular
     matrix R and the m by n strictly lower triangular part of A
     will contain details of the factorization as described in
     Section 3.

 4:  LDA -- INTEGER                                        Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which F01QCF is called.
     Constraint: LDA >= max(1,M).

 5:  ZETA(*) -- DOUBLE PRECISION array                    Output
     Note: the dimension of the array ZETA must be at least max
     (1,n) On exit: ZETA(k) contains the scalar (zeta)  for the k
                                                      k
     th transformation. If T =I then ZETA(k)=0.0, otherwise ZETA(
```

k) contains $(\zeta)_k^k$ as described in Section 3 and $(\zeta)_k$ is always in the range $(1.0, \sqrt{2.0})$.

6: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL=-1
On entry M < N,

or N < 0,

or LDA < M.

7. Accuracy

The computed factors Q and R satisfy the relation

$$Q\begin{pmatrix}R\\0\end{pmatrix}=A+E,$$

where

$$|||E|||\le c(\epsilon)|||A|||,$$

and (ϵ) is the machine precision (see X02AJF(*)), c is a modest function of m and n and |||.||| denotes the spectral (two) norm.

8. Further Comments

The approximate number of floating-point operations is given by $2n^2(3m-n)/3$.

Following the use of this routine the operations

$$B:=QB \quad\text{and}\quad B:=Q^T B,$$

where B is an m by k matrix, can be performed by calls to F01QDF. The operation B:=QB can be obtained by the call:

```
      IFAIL = 0
      CALL F01QDF('No transpose', 'Separate', M, N, A, LDA, ZETA,
     *            K, B, LDB, WORK, IFAIL)
```

and $B:=Q^T B$ can be obtained by the call:

```
      IFAIL = 0
      CALL F01QDF('Transpose', 'Separate', M, N, A, LDA, ZETA,
     *            K, B, LDB, WORK, IFAIL)
```

In both cases WORK must be a k element array that is used as workspace. If B is a one-dimensional array (single column) then the parameter LDB can be replaced by M. See F01QDF for further details.

The first k columns of the orthogonal matrix Q can either be obtained by setting B to the first k columns of the unit matrix and using the first of the above two calls, or by calling F01QEF, which overwrites the k columns of Q on the first k columns of the array A. Q is obtained by the call:

```
     CALL F01QEF('Separate', M, N, K, A, LDA, ZETA, WORK, IFAIL)
```

As above WORK must be a k element array. If k is larger than N, then A must have been declared to have at least k columns.

Operations involving the matrix R can readily be performed by the Level 2 BLAS routines DTRSV and DTRMV (see Chapter F06), but note that no test for near singularity of R is incorporated in DTRSV. If R is singular, or nearly singular then F02WUF(*) can be used to determine the singular value decomposition of R.

9. Example

To obtain the QR factorization of the 5 by 3 matrix

```
                       (2.0  2.5  2.5)
                       (2.0  2.5  2.5)
                     A=(1.6 -0.4  2.8).
```

```
                              (2.0 -0.5  0.5)
                              (1.2 -0.3 -2.9)

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

\end{verbatim}
\endscroll
\end{page}
```

————-

16.5.8 $B := QB$ or $B := Q^T B$

— nagf.ht —

```
\begin{page}{manpageXXf01qdf}{NAG Documentation: f01qdf}
\beginscroll
\begin{verbatim}

     F01QDF(3NAG)      Foundation Library (12/10/92)      F01QDF(3NAG)

          F01 -- Matrix Factorizations                            F01QDF
                  F01QDF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F01QDF performs one of the transformations

                                             T
                              B:=QB or B:=Q B,

          where B is an m by ncolb real matrix and Q is an m by m
          orthogonal matrix, given as the product of Householder
          transformation matrices.

          This routine is intended for use following F01QCF or F01QFF(*).
```

2. Specification

```
       SUBROUTINE F01QDF (TRANS, WHERET, M, N, A, LDA, ZETA,
      1                   NCOLB, B, LDB, WORK, IFAIL)
       INTEGER          M, N, LDA, NCOLB, LDB, IFAIL
       DOUBLE PRECISION A(LDA,*), ZETA(*), B(LDB,*), WORK(*)
       CHARACTER*1      TRANS, WHERET
```

3. Description

Q is assumed to be given by

$$Q=(Q_n Q_{n-1} ...Q_1)^T,$$

Q_k being given in the form

$$Q_k=\begin{pmatrix} I & 0 \\ 0 & T_k \end{pmatrix}$$

where

$$T_k=I-u_k u_k^T,$$

$$u_k=\begin{pmatrix} (zeta)_k \\ z_k \end{pmatrix},$$

$(zeta)_k$ is a scalar and z_k is an (m-k) element vector. z_k must be supplied in the kth column of A in elements A(k+1,k),...,A(m,k) and $(zeta)_k$ must be supplied either in A(k,k) or in ZETA(k), depending upon the parameter WHERET.

To obtain Q explicitly B may be set to I and pre-multiplied by Q. This is more efficient than obtaining Q^T.

4. References

[1] Golub G H and Van Loan C F (1989) Matrix Computations (2nd Edition). Johns Hopkins University Press, Baltimore,

Maryland.

[2] Wilkinson J H (1965) The Algebraic Eigenvalue Problem. Oxford University Press.

5. Parameters

1: TRANS -- CHARACTER*1 Input

On entry: the operation to be performed as follows:

TRANS = 'N' (No transpose)

Perform the operation B:=QB.

TRANS = 'T' or 'C' (Transpose)

Perform the operation B:=Q^T B.

Constraint: TRANS must be one of 'N', 'T' or 'C'.

2: WHERET -- CHARACTER*1 Input

On entry: indicates where the elements of (zeta) are to be found as follows:

WHERET = 'I' (In A)

The elements of (zeta) are in A.

WHERET = 'S' (Separate)

The elements of (zeta) are separate from A, in ZETA.

Constraint: WHERET must be one of 'I' or 'S'.

3: M -- INTEGER Input

On entry: m, the number of rows of A. Constraint: M >= N.

4: N -- INTEGER Input

On entry: n, the number of columns of A.

When N = 0 then an immediate return is effected.

Constraint: N >= 0.

5: A(LDA,*) -- DOUBLE PRECISION array Input

Note: the second dimension of the array A must be at least max(1,N).

On entry: the leading m by n strictly lower triangular part of the array A must contain details of the matrix Q. In addition, when WHERET = 'I', then the diagonal elements of A must contain the elements of (zeta) as described under the argument ZETA below.

When WHERET = 'S', the diagonal elements of the array A are referenced, since they are used temporarily to store the $(zeta)_k$, but they contain their original values on return.

```
 6:  LDA -- INTEGER                                         Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which F01QDF is called.
     Constraint: LDA >= max(1,M).

 7:  ZETA(*) -- DOUBLE PRECISION array                      Input
     Note: when WHERET = 'S', the dimension of the array ZETA
     must be greater than or equal to max(1,N). On entry: if
     WHERET = 'S', the array ZETA must contain the elements of
     (zeta). If ZETA(k) = 0.0 then T  is assumed to be I
                                    k
     otherwise ZETA(k) is assumed to contain (zeta) .
                                                   k

     When WHERET = 'I', ZETA is not referenced.

 8:  NCOLB -- INTEGER                                       Input
     On entry: ncolb, number of columns of B.

     When NCOLB = 0 then an immediate return is effected.
     Constraint: NCOLB >= 0.

 9:  B(LDB,*) -- DOUBLE PRECISION array              Input/Output
     Note: the second dimension of the array B must be at least
     max(1,NCOLB).
     On entry: the leading m by ncolb part of the array B must
     contain the matrix to be transformed. On exit: B is
     overwritten by the transformed matrix.

10:  LDB -- INTEGER                                         Input
     On entry:
     the first dimension of the array B as declared in the
     (sub)program from which F01QDF is called.
     Constraint: LDB >= max(1,M).

11:  WORK(*) -- DOUBLE PRECISION array                  Workspace
     Note: the dimension of the array WORK must be at least
     max(1,NCOLB).

12:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings
```

```
Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL=-1
     On entry TRANS /= 'N', 'T' or 'C',

     or       WHERET /= 'I' or 'S',

     or       M < N,

     or       N < 0,

     or       LDA < M,

     or       NCOLB < 0,

     or       LDB < M.

7. Accuracy

                                      T
Letting C denote the computed matrix Q B, C satisfies the
relation

                             QC=B+E,

where

                    ||E||<=c(epsilon)||B||,

and (epsilon) the machine precision (see X02AJF(*)), c is a
modest function of m and |||.||| denotes the spectral (two) norm.
An equivalent result holds for the computed matrix QB. See also
Section 7 of F01QCF.

8. Further Comments

The approximate number of floating-point operations is given by
2n(2m-n)ncolb.

9. Example

                    T
To obtain the matrix Q B for the matrix B given by

                           ( 1.1  0.00)
                           ( 0.9  0.00)
                        B=( 0.6  1.32)
```

```
                                 ( 0.0  1.10)
                                 (-0.8 -0.26)

          following the QR factorization of the 5 by 3 matrix A given by

                                 (2.0  2.5  2.5)
                                 (2.0  2.5  2.5)
                               A=(1.6 -0.4  2.8).
                                 (2.0 -0.5  0.5)
                                 (1.2 -0.3 -2.9)

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

\begin{verbatim}

     F01QEF(3NAG)      Foundation Library (12/10/92)      F01QEF(3NAG)

          F01 -- Matrix Factorizations                              F01QEF
                  F01QEF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F01QEF returns the first ncolq columns of the real m by m
          orthogonal matrix Q, where Q is given as the product of
```

Householder transformation matrices.

This routine is intended for use following F01QCF or F01QFF(*).

2. Specification

```
       SUBROUTINE F01QEF (WHERET, M, N, NCOLQ, A, LDA, ZETA,
      1                   WORK, IFAIL)
       INTEGER          M, N, NCOLQ, LDA, IFAIL
       DOUBLE PRECISION A(LDA,*), ZETA(*), WORK(*)
       CHARACTER*1      WHERET
```

3. Description

Q is assumed to be given by

$$Q=(Q_n Q_{n-1} ...Q_1)^T,$$

Q_k being given in the form

$$Q_k=\begin{pmatrix} I & 0 \\ 0 & T_k \end{pmatrix}$$

where

$$T_k=I-u_k u_k^T,$$

$$u_k=\begin{pmatrix} (zeta)_k \\ z_k \end{pmatrix},$$

$(zeta)_k$ is a scalar and z_k is an (m-k) element vector. z_k must be supplied in the kth column of A in elements A(k+1,k),...,A(m,k) and $(zeta)_k$ must be supplied either in A(k,k) or in ZETA(k), depending upon the parameter WHERET.

4. References

[1] Golub G H and Van Loan C F (1989) Matrix Computations (2nd Edition). Johns Hopkins University Press, Baltimore, Maryland.

```
[2]  Wilkinson J H (1965) The Algebraic Eigenvalue Problem.
     Oxford University Press.

5. Parameters

 1:  WHERET -- CHARACTER*1                              Input
     On entry: indicates where the elements of (zeta) are to be
     found as follows:
     WHERET = 'I' (In A)
           The elements of (zeta) are in A.

     WHERET = 'S' (Separate)
           The elements of (zeta) are separate from A, in ZETA.
     Constraint: WHERET must be one of 'I' or 'S'.

 2:  M -- INTEGER                                       Input
     On entry: m, the number of rows of A. Constraint: M >= N.

 3:  N -- INTEGER                                       Input
     On entry: n, the number of columns of A. Constraint: N >=
     0.

 4:  NCOLQ -- INTEGER                                   Input
     On entry: ncolq, the required number of columns of Q.
     Constraint: 0 <= NCOLQ <= M.

     When NCOLQ = 0 then an immediate return is effected.

 5:  A(LDA,*) -- DOUBLE PRECISION array          Input/Output
     Note: the second dimension of the array A must be at least
     max(1,N,NCOLQ).
     On entry: the leading m by n strictly lower triangular part
     of the array A must contain details of the matrix Q. In
     addition, when WHERET = 'I', then the diagonal elements of A
     must contain the elements of (zeta) as described under the
     argument ZETA below. On exit: the first NCOLQ columns of the
     array A are overwritten by the first NCOLQ columns of the m
     by m orthogonal matrix Q. When N = 0 then the first NCOLQ
     columns of A are overwritten by the first NCOLQ columns of
     the identity matrix.

 6:  LDA -- INTEGER                                     Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which F01QEF is called.
     Constraint: LDA >= max(1,M).

 7:  ZETA(*) -- DOUBLE PRECISION array                  Input
     Note: the dimension of the array ZETA must be at least
     max(1,N).
     On entry: with WHERET = 'S', the array ZETA must contain the
     elements of (zeta). If ZETA(k) = 0.0 then T  is assumed to
                                                k
     be I, otherwise ZETA(k) is assumed to contain (zeta) .
                                                          k

     When WHERET = 'I', the array ZETA is not referenced.

 8:  WORK(*) -- DOUBLE PRECISION array                  Workspace
     Note: the dimension of the array WORK must be at least
     max(1,NCOLQ).

 9:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL=-1
     On entry WHERET /= 'I' or 'S',

     or       M < N,

     or       N < 0,

     or       NCOLQ < 0 or NCOLQ > M,

     or       LDA < M.

7. Accuracy

The computed matrix Q satisfies the relation

                             Q=P+E,

where P is an exactly orthogonal matrix and

                       ||E||<=c(epsilon)

(epsilon) is the machine precision (see X02AJF(*)), c is a modest
```

```
          function of m and |||.||| denotes the spectral (two) norm. See
          also Section 7 of F01QCF.

          8. Further Comments

          The approximate number of floating-point operations required is
          given by

               2
               -n{(3m-n)(2ncolq-n)-n(ncolq-n)},    ncolq>n,
               3

               2     2
               -ncolq (3m-ncolq),                  ncolq<=n.
               3

          9. Example

          To obtain the 5 by 5 orthogonal matrix Q following the QR
          factorization of the 5 by 3 matrix A given by

                                    (2.0  2.5  2.5)
                                    (2.0  2.5  2.5)
                                  A=(1.6 -0.4  2.8).
                                    (2.0 -0.5  0.5)
                                    (1.2 -0.3 -2.9)

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

```

F01 -- Matrix Factorizations   F01RCF

F01RCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F01RCF finds the QR factorization of the complex m by n matrix A, where m>=n.

2. Specification

```
       SUBROUTINE   F01RCF (M, N, A, LDA, THETA, IFAIL)
       INTEGER             M, N, LDA, IFAIL
       COMPLEX(KIND(1.0D0)) A(LDA,*), THETA(*)
```

3. Description

The m by n matrix A is factorized as

$$A=Q\begin{pmatrix}R\\0\end{pmatrix} \quad \text{when } m>n,$$

$$A=QR \quad \text{when } m=n,$$

where Q is an m by m unitary matrix and R is an n by n upper triangular matrix with real diagonal elements.

The factorization is obtained by Householder's method. The kth transformation matrix, Q_k, which is used to introduce zeros into the kth column of A is given in the form

$$Q_k=\begin{pmatrix}I & 0\\0 & T_k\end{pmatrix},$$

where

$$T_k=I-\gamma_k u_k u_k^H,$$

$$u_k = \begin{pmatrix} \zeta_k \\ z_k \end{pmatrix},$$

γ_k is a scalar for which $\mathrm{Re}\,\gamma_k = 1.0$, ζ_k is a real scalar and z_k is an (m-k) element vector. γ_k, ζ_k and z_k are chosen to annihilate the elements below the triangular part of A and to make the diagonal elements real.

The scalar γ_k and the vector u_k are returned in the kth element of the array THETA and in the kth column of A, such that θ_k, given by

$$\theta_k = (\zeta_k, \mathrm{Im}\,\gamma_k),$$

is in THETA(k) and the elements of z_k are in $a_{k+1,k},\ldots,a_{m,k}$. The elements of R are returned in the upper triangular part of A.

Q is given by

$$Q = (Q_n Q_{n-1} \ldots Q_1)^H.$$

A good background description to the QR factorization is given in Dongarra et al [1], but note that this routine is not based upon LINPACK routine ZQRDC.

[2] Wilkinson J H (1965) The Algebraic Eigenvalue Problem. Oxford University Press.

5. Parameters

1: M -- INTEGER Input
On entry: m, the number of rows of A. Constraint: M >= N.

2: N -- INTEGER Input

```
     On entry: n, the number of columns of A. Constraint: N >=
     0.

     When N = 0 then an immediate return is effected.

 3:  A(LDA,*) -- COMPLEX(KIND(1.0D0)) array          Input/Output
     Note: the second dimension of the array A must be at least
     max(1,N).
     On entry: the leading m by n part of the array A must
     contain the matrix to be factorized. On exit: the n by n
     upper triangular part of A will contain the upper triangular
     matrix R, with the imaginary parts of the diagonal elements
     set to zero, and the m by n strictly lower triangular part
     of A will contain details of the factorization as described
     above.

 4:  LDA -- INTEGER                                         Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which F01RCF is called.
     Constraint: LDA >= max(1,M).

 5:  THETA(*) -- COMPLEX(KIND(1.0D)) array                 Output
     Note: the dimension of the array THETA must be at least
     max(1,N).
     On exit: the scalar (theta)  for the kth transformation. If
                                k
     T =I then THETA(k) = 0.0; if
      k
                      ((alpha) 0)
                   T =(      0 I)   Re(alpha)<0.0,
                    k
     then THETA(k)=(alpha); otherwise THETA(k) contains THETA(k)
     as described in Section 3 and Re(THETA(k)) is always in the

     range (1.0, \/2.0).

 6:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:
```

```
If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL=-1
     On entry M < N,

     or       N < 0,

     or       LDA < M.

7. Accuracy
The computed factors Q and R satisfy the relation

                             (R)
                            Q(0)=A+E,

where

                  ||E||<=c(epsilon)||A||,

(epsilon) being the machine precision, c is a modest function of
m and n and ||.|| denotes the spectral (two) norm.

8. Further Comments

The approximate number of real floating-point operations is given
     2
by 8n (3m-n)/3.

Following the use of this routine the operations

                                        H
                       B:=QB  and  B:=Q B,

where B is an m by k matrix, can be performed by calls to F01RDF.
The operation B:=QB can be obtained by the call:

      IFAIL = 0
      CALL F01RDF('No conjugate', 'Separate', M, N, A, LDA, THETA,
     *            K, B, LDB, WORK, IFAIL)

        H
and B:=Q B can be obtained by the call:

      IFAIL = 0
      CALL F01RDF('Conjugate', 'Separate', M, N, A, LDA, THETA,
     *            K, B, LDB, WORK, IFAIL)
```

```
          In both cases WORK must be a k element array that is used as
          workspace. If B is a one-dimensional array (single column) then
          the parameter LDB can be replaced by M. See F01RDF for further
          details.

          The first k columns of the unitary matrix Q can either be
          obtained by setting B to the first k columns of the unit matrix
          and using the first of the above two calls, or by calling F01REF,
          which overwrites the k columns of Q on the first k columns of the
          array A. Q is obtained by the call:

                CALL F01REF('Separate', M, N, K, A, LDA, THETA, WORK, IFAIL)

          As above, WORK must be a k element array. If k is larger than n,
          then A must have been declared to have at least k columns.

          Operations involving the matrix R can readily be performed by the
          Level 2 BLAS routines ZTRSV and ZTRMV (see Chapter F06), but note
          that no test for near singularity of R is incorporated in ZTRSV.
          If R is singular, or nearly singular, then F02XUF(*) can be used
          to determine the singular value decomposition of R.

          9. Example

          To obtain the QR factorization of the 5 by 3 matrix

                           (  0.5i -0.5+1.5i -1.0+1.0i)
                           (0.4+0.3i 0.9+1.3i 0.2+1.4i)
                         A=(  0.4 -0.4+0.4i    1.8    ).
                           (0.3-0.4i 0.1+0.7i    0.0  )
                           ( -0.3i 0.3+0.3i   2.4i    )

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

     F01RDF(3NAG)      Foundation Library (12/10/92)      F01RDF(3NAG)

          F01 -- Matrix Factorizations                               F01RDF
                  F01RDF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F01RDF performs one of the transformations

                                                     H
                                        B:=QB or B:=Q B,

          where B is an m by ncolb complex matrix and Q is an m by m
          unitary matrix, given as the product of Householder
          transformation matrices.

          This routine is intended for use following F01RCF or F01RFF(*).

          2. Specification

                 SUBROUTINE F01RDF (TRANS, WHERET, M, N, A, LDA, THETA,
                1                   NCOLB, B, LDB, WORK, IFAIL)
                 INTEGER              M, N, LDA, NCOLB, LDB, IFAIL
                 COMPLEX(KIND(1.0D0)) A(LDA,*), THETA(*), B(LDB,*), WORK(*)
                 CHARACTER*1          TRANS, WHERET

          3. Description

          The unitary matrix Q is assumed to be given by

                                                       H
                                        Q=(Q Q   ...Q ) ,
                                            n n-1    1

          Q  being given in the form
           k
```

$$Q_k = \begin{pmatrix} I & 0 \\ 0 & T_k \end{pmatrix},$$

where

$$T_k = I - \gamma_k u_k u_k^H,$$

$$u_k = \begin{pmatrix} \zeta_k \\ z_k \end{pmatrix},$$

γ_k is a scalar for which Re $\gamma_k = 1.0$, ζ_k is a real scalar and z_k is an (m-k) element vector.

z_k must be supplied in the kth column of A in elements $a_{k+1,k},\ldots,a_{m,k}$ and θ_k, given by

$$\theta_k = (\zeta_k, \text{Im } \gamma_k),$$

must be supplied either in $a_{k,k}$ or in THETA(k), depending upon the parameter WHERET.

To obtain Q explicitly B may be set to I and pre-multiplied by Q. This is more efficient than obtaining Q^H. Alternatively, F01REF may be used to obtain Q overwritten on A.

4. References

[1] Wilkinson J H (1965) The Algebraic Eigenvalue Problem. Oxford University Press.

5. Parameters

1: TRANS -- CHARACTER*1 Input

On entry: the operation to be performed as follows:

TRANS = 'N' (No transpose)
    Perform the operation B:=QB.

TRANS = 'C' (Conjugate transpose)

```
                                   H
      Perform the operation B:=Q B.
Constraint: TRANS must be one of 'N' or 'C'.

2:  WHERET -- CHARACTER*1                                 Input
    On entry: the elements of (theta) are to be found as
    follows:
    WHERET = 'I' (In A)
          The elements of (theta) are in A.

    WHERET = 'S' (Separate)
          The elements of (theta) are separate from A, in THETA.
    Constraint: WHERET must be one of 'I' or 'S'.

3:  M -- INTEGER                                          Input
    On entry: m, the number of rows of A. Constraint: M >= N.

4:  N -- INTEGER                                          Input
    On entry: n, the number of columns of A. Constraint: N >=
    0.

    When N = 0 then an immediate return is effected.

5:  A(LDA,*) -- COMPLEX(KIND(1.0D)) array                 Input
    Note: the second dimension of the array A must be at least
    max(1,N).
    On entry: the leading m by n strictly lower triangular part
    of the array A must contain details of the matrix Q. In
    addition, when WHERET = 'I', then the diagonal elements of A
    must contain the elements of (theta) as described under the
    argument THETA below.

    When WHERET = 'S', then the diagonal elements of the array A
    are referenced, since they are used temporarily to store the
    (zeta) , but they contain their original values on return.
          k

6:  LDA -- INTEGER                                        Input
    On entry:
    the first dimension of the array A as declared in the
    (sub)program from which F01RDF is called.
    Constraint: LDA >= max(1,M).

7:  THETA(*) -- COMPLEX(KIND(1.0D)) array                 Input
    Note: the dimension of the array THETA must be at least
    max(1,N).
    On entry: with WHERET = 'S', the array THETA must contain
    the elements of (theta). If THETA(k)=0.0 then T  is assumed
                                                   k
    to be I; if THETA(k)=(alpha), with Re(alpha)<0.0, then T  is
```

```
                                                       k
     assumed to be of the form
                          ((alpha) 0)
                      T =(0       I);
                       k
     otherwise THETA(k) is assumed to contain (theta)  given by
                                                   k
     (theta) =((zeta) ,Im(gamma) ).
            k       k          k

     When WHERET = 'I', the array THETA is not referenced, and
     may be dimensioned of length 1.

 8:  NCOLB -- INTEGER                                      Input
     On entry: ncolb, the number of columns of B. Constraint:
     NCOLB >= 0.
     When NCOLB = 0 then an immediate return is effected.

 9:  B(LDB,*) -- COMPLEX(KIND(1.0D)) array          Input/Output
     Note: the second dimension of the array B must be at least
     max(1,NCOLB).
     On entry: the leading m by ncolb part of the array B must
     contain the matrix to be transformed. On exit: B is
     overwritten by the transformed matrix.

10:  LDB -- INTEGER                                        Input
     On entry:
     the first dimension of the array B as declared in the
     (sub)program from which F01RDF is called.
     Constraint: LDB >= max(1,M).

11:  WORK(*) -- COMPLEX(KIND(1.0D)) array              Workspace
     Note: the dimension of the array WORK must be at least
     max(1,NCOLB).

12:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).
```

```
IFAIL=-1
     On entry TRANS /= 'N' or 'C',

     or       WHERET /= 'I' or 'S',

     or       M < N,

     or       N < 0,

     or       LDA < M,

     or       NCOLB < 0,

     or       LDB < M.

7. Accuracy

Letting C denote the computed matrix Q B, C satisfies the
relation

                             QC=B+E,

where

                   ||E||<=c(epsilon)||B||,

(epsilon) being the machine precision, c is a modest function of
m and |||.||| denotes the spectral (two) norm. An equivalent
result holds for the computed matrix QB. See also Section 7 of
F01RCF.

8. Further Comments

The approximate number of real floating-point operations is given
by 8n(2m-n)ncolb.

9. Example

                      H
To obtain the matrix Q B for the matrix B given by

                     (-0.55+1.05i  0.45+1.05i)
                     ( 0.49+0.93i  1.09+0.13i)
                   B=( 0.56-0.16i  0.64+0.16i)
                     ( 0.39+0.23i -0.39-0.23i)
                     ( 1.13+0.83i -1.13+0.77i)

following the QR factorization of the 5 by 3 matrix A given by

                   (  0.5i   -0.5+1.5i -1.0+1.0i)
```

```
                          (0.4+0.3i  0.9+1.3i  0.2+1.4i)
                        A=(  0.4    -0.4+0.4i  1.8     ).
                          (0.3-0.4i  0.1+0.7i  0.0     )
                          ( -0.3i    0.3+0.3i      2.4i)

\begin{verbatim}

     F01REF(3NAG)      Foundation Library (12/10/92)      F01REF(3NAG)

          F01 -- Matrix Factorizations                               F01REF
                  F01REF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F01REF returns the first ncolq columns of the complex m by m
          unitary matrix Q, where Q is given as the product of Householder
          transformation matrices.

          This routine is intended for use following F01RCF.

          2. Specification
```

```
       SUBROUTINE F01REF (WHERET, M, N, NCOLQ, A, LDA, THETA,
      1                   WORK, IFAIL)
       INTEGER              M, N, NCOLQ, LDA, IFAIL
       COMPLEX(KIND(1.0D0)) A(LDA,*), THETA(*), WORK(*)
       CHARACTER*1          WHERET
```

3. Description

The unitary matrix Q is assumed to be given by

$$Q=(Q_n Q_{n-1} ... Q_1)^H ,$$

Q_k being given in the form

$$Q_k=\begin{pmatrix} I & 0 \\ 0 & T_k \end{pmatrix},$$

where

$$T_k=I-\gamma_k u_k u_k^H ,$$

$$u_k=\begin{pmatrix} \zeta_k \\ z_k \end{pmatrix},$$

γ_k is a scalar for which Re γ_k =1.0, ζ_k is a real scalar and z_k is an (m-k) element vector.

z_k must be supplied in the kth column of A in elements $a_{k+1,k},...,a_{m,k}$ and θ_k, given by

$$\theta_k=(\zeta_k, \mathrm{Im}\ \gamma_k),$$

must be supplied either in $a_{k,k}$ or in THETA(k) depending upon the parameter WHERET.

```
4. References

[1]   Wilkinson J H (1965) The Algebraic Eigenvalue Problem.
      Oxford University Press.

5. Parameters

 1:  WHERET -- CHARACTER*1                                    Input
     On entry: the elements of (theta) are to be found as
     follows:
     WHERET = 'I' (In A)
           The elements of (theta) are in A.

     WHERET = 'S' (Separate)
           The elements of (theta) are separate from A, in THETA.
     Constraint: WHERET must be one of 'I' or 'S'.

 2:  M -- INTEGER                                             Input
     On entry: m, the number of rows of A. Constraint: M >= N.

 3:  N -- INTEGER                                             Input
     On entry: n, the number of columns of A. Constraint: N >=
     0.

 4:  NCOLQ -- INTEGER                                         Input
     On entry: ncolq, the required number of columns of Q.
     Constraint: 0 <= NCOLQ <= M.

     When NCOLQ = 0 then an immediate return is effected.

 5:  A(LDA,*) -- COMPLEX(KIND(1.0D)) array             Input/Output
     Note: the second dimension of the array A must be at least
     max(1,N,NCOLQ).
     On entry: the leading m by n strictly lower triangular part
     of the array A must contain details of the matrix Q. In
     addition, when WHERET = 'I', then the diagonal elements of A
     must contain the elements of (theta) as described under the
     argument THETA below. On exit: the first NCOLQ columns of
     the array A are overwritten by the first NCOLQ columns of
     the m by m unitary matrix Q. When N = 0 then the first NCOLQ
     columns of A are overwritten by the first NCOLQ columns of
     the unit matrix.

 6:  LDA -- INTEGER                                           Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which F01REF is called.
     Constraint: LDA >= max(1,M).

 7:  THETA(*) -- COMPLEX(KIND(1.0D)) array                    Input
```

```
    Note: the dimension of the array THETA must be at least
    max(1,N).
    On entry: if WHERET = 'S', the array THETA must contain the
    elements of (theta). If THETA(k)=0.0 then T  is assumed to
                                               k
    be I; if THETA(k)=(alpha), with Re(alpha)<0.0, then T  is
                                                         k
    assumed to be of the form
                         ((alpha) 0)
                      T =(   0    I);
                       k
    otherwise THETA(k) is assumed to contain (theta)  given by
                                                    k
    (theta) =((zeta) ,Im(gamma) ).
           k        k          k

    When WHERET = 'I', the array THETA is not referenced.

 8: WORK(*) -- COMPLEX(KIND(1.0D)) array               Workspace
    Note: the dimension of the array WORK must be at least
    max(1,NCOLQ).

 9: IFAIL -- INTEGER                                Input/Output
    On entry: IFAIL must be set to 0, -1 or 1. For users not
    familiar with this parameter (described in the Essential
    Introduction) the recommended value is 0.

    On exit: IFAIL = 0 unless the routine detects an error (see
    Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL=-1
    On entry WHERET /= 'I' or 'S',

    or      M < N,

    or      N < 0,

    or      NCOLQ < 0 or NCOLQ > M,

    or      LDA < M.

7. Accuracy
```

```
          The computed matrix Q satisfies the relation

                                   Q=P+E,

          where P is an exactly unitary matrix and

                               ||E||<=c(epsilon),

          (epsilon) being the machine precision, c is a modest function of
          m and |||.||| denotes the spectral (two) norm. See also Section 7
          of F01RCF.

          8. Further Comments

          The approximate number of real floating-point operations required
          is given by

               8
               -n{(3m-n)(2ncolq-n)-n(ncolq-n)},  ncolq>n
               3

               8     2
               -ncolq (3m-ncolq),                ncolq<=n
               3

          9. Example

          To obtain the 5 by 5 unitary matrix Q following the QR
          factorization of the 5 by 3 matrix A given by

                             (    0.5i -0.5+1.5i -1.0+1.4i)
                             (0.4+0.3i  0.9+1.3i  0.2+1.4i)
                           A=(0.4      -0.4+0.4i  1.8     ).
                             (0.3-0.4i  0.1+0.7i  0.0     )
                             (   -0.3i  0.3+0.3i      2.4i)

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

     F02(3NAG)         Foundation Library (12/10/92)         F02(3NAG)

          F02 -- Eigenvalues and Eigenvectors           Introduction -- F02
                                       Chapter F02
                              Eigenvalues and Eigenvectors

          1. Scope of the Chapter

          This chapter is concerned with computing

          --    eigenvalues and eigenvectors of a matrix

          --    eigenvalues and eigenvectors of generalized matrix
                eigenvalue problems

          --    singular values and singular vectors of a matrix.

          2. Background to the Problems

          2.1. Eigenvalue Problems

          In the most usual form of eigenvalue problem we are given a
          square n by n matrix A and wish to compute (lambda) (an
          eigenvalue) and x/=0 (an eigenvector) which satisfy the equation

                                       Ax=(lambda)x

          Such problems are called 'standard' eigenvalue problems in
          contrast to 'generalized' eigenvalue problems where we wish to
          satisfy the equation

                                       Ax=(lambda)Bx

          B also being a square n by n matrix.

          Section 2.1.1 and Section 2.1.2 discuss, respectively, standard
          and generalized eigenvalue problems where the matrices involved
```

are dense; Section 2.1.3 discusses both types of problem in the case where A and B are sparse (and symmetric).

2.1.1. Standard eigenvalue problems

Some of the routines in this chapter find all the n eigenvalues, some find all the n eigensolutions (eigenvalues and corresponding eigenvectors), and some find a selected group of eigenvalues and/or eigenvectors. The matrix A may be:

(i) general (real or complex)

(ii) real symmetric, or

(iii) complex Hermitian (so that if a_{ij}=(alpha)+i(beta) then a_{ji}=(alpha)-i(beta)).

In all cases the computation starts with a similarity transformation $S^{-1}AS=T$, where S is non-singular and is the product of fairly simple matrices, and T has an 'easier form' than A so that its eigensolutions are easily determined. The matrices A and T, of course, have the same eigenvalues, and if y is an eigenvector of T then Sy is the corresponding eigenvector of A.

In case (i) (general real or complex A), the selected form of T is an upper Hessenberg matrix (t_{ij}=0 if i-j>1) and S is the product of n-2 stabilised elementary transformation matrices. There is no easy method of computing selected eigenvalues of a Hessenberg matrix, so that all eigenvalues are always calculated. In the real case this computation is performed via the Francis QR algorithm with double shifts, and in the complex case by means of the LR algorithm. If the eigenvectors are required they are computed by back-substitution following the QR and LR algorithm.

In case (ii) (real and symmetric A) the selected simple form of T is a tridiagonal matrix (t_{ij}=0 if |i-j|>1), and S is the product of n-2 orthogonal Householder transformation matrices. If only selected eigenvalues are required, they are obtained by the method of bisection using the Sturm sequence property, and the corresponding eigenvectors of T are computed by inverse iteration. If all eigenvalues are required, they are computed from T via the QL algorithm (an adaptation of the QR algorithm), and the corresponding eigenvectors of T are the product of the transformations for the QL reduction. In all cases the corresponding eigenvectors of A are recovered from the computation of x=Sy.

In case (iii) (complex Hermitian A) analogous transformations as in case (ii) are used. T has complex elements in off-diagonal positions, but a simple diagonal similarity transformation is then used to produce a real tridiagonal form, after which the QL algorithm and succeeding methods described in the previous paragraph are used to complete the solution.

2.1.2. Generalized eigenvalue problems

Here we distinguish as a special case those problems in which both A and B are symmetric and B is positive-definite and well-conditioned with respect to inversion (i.e., all the eigenvalues of B are significantly greater than zero). Such problems can be satisfactorily treated by first reducing them to case (ii) of Section 2.1.1 and then using the methods described there to compute the eigensolutions. If B is factorized as LL^T (L lower triangular), then Ax=(lambda)Bx is equivalent to the standard symmetric problem Ry=(lambda)y, where $R=L^{-1}A(L^T)^{-1}$ and $y=L^T x$. After finding an eigenvector y of R, the required x is computed by back-substitution in $y=L^T x$.

For generalized problems of the form Ax=(lambda)Bx which do not fall into the special case, the QZ algorithm is provided.

In order to appreciate the domain in which this algorithm is appropriate we remark first that when B is non-singular the problem Ax=(lambda)Bx is fully equivalent to the problem $(B^{-1}A)x=(lambda)x$; both the eigenvalues and eigenvectors being the same. When A is non-singular Ax=(lambda)Bx is equivalent to the problem $(A^{-1}B)x=(mu)x$; the eigenvalues (mu) being the reciprocals of the required eigenvalues and the eigenvectors remaining the same. In theory then, provided at least one of the matrices A and B is non-singular, the generalized problem Ax=(lambda)Bx could be solved via the standard problem Cx=(lambda)x with an appropriate matrix C, and as far as economy of effort is concerned this is quite satisfactory. However, in practice, for this reduction to be satisfactory from the standpoint of numerical stability, one requires more than the mere non-singularity of A or B. It is necessary that $B^{-1}A$ (or $A^{-1}B$) should not only exist but that B (or A) should be well-conditioned with respect to inversion. The nearer B (or A) is to singularity the more unsatisfactory $B^{-1}A$ (or $A^{-1}B$) will be as a vehicle for determining the required eigenvalues. Unfortunately one cannot counter ill-conditioning in B (or A) by computing $B^{-1}A$ (or $A^{-1}B$) accurately to single precision using iterative refinement. Well-determined eigenvalues of the original Ax=(lambda)Bx may be poorly determined even by the correctly rounded version of $B^{-1}A$ (or $A^{-1}B$). The situation may in some instances be saved by the observation that if Ax=(lambda)Bx then (A-kB)x=((lambda)-k)Bx. Hence if A-kB is non-singular we may solve the standard problem $[(A-kB)^{-1}B]x=(mu)x$ and for numerical stability we require only that (A-kB) be well-conditioned with respect to inversion.

In practice one may well be in a situation where no k is known for which (A-kB) is well-conditioned with respect to inversion and indeed (A-kB) may be singular for all k. The QZ algorithm is designed to deal directly with the problem Ax=(lambda)Bx itself and its performance is unaffected by singularity or near-singularity of A, B or A-kB.

2.1.3. Sparse symmetric problems

If the matrices A and B are large and sparse (i.e., only a small proportion of the elements are non-zero), then the methods described in the previous Section are unsuitable, because in reducing the problem to a simpler form, much of the sparsity of the problem would be lost; hence the computing time and the storage required would be very large. Instead, for symmetric problems, the method of simultaneous iteration may be used to determine selected eigenvalues and the corresponding eigenvectors. The routine provided has been designed to handle both symmetric and generalized symmetric problems.

2.2. Singular Value Problems

The singular value decomposition of an m by n real matrix A is given by

$$A=QDP^T,$$

where Q is an m by m orthogonal matrix, P is an n by n orthogonal matrix and D is an m by n diagonal matrix with non-negative diagonal elements. The first k==min(m,n) columns of Q and P are the left- and right-hand singular vectors of A and the k diagonal elements of D are the singular values.

When A is complex then the singular value decomposition is given by

$$A=QDP^H,$$

where Q and P are unitary, P^H denotes the complex conjugate of P^T and D is as above for the real case.

If the matrix A has column means of zero, then AP is the matrix of principal components of A and the singular values are the square roots of the sample variances of the observations with respect to the principal components. (See also Chapter G03.)

Routines are provided to return the singular values and vectors of a general real or complex matrix.

3. Recommendations on Choice and Use of Routines

3.1. General Discussion

There is one routine, F02FJF, which is designed for sparse symmetric eigenvalue problems, either standard or generalized. The remainder of the routines are designed for dense matrices.

3.2. Eigenvalue and Eigenvector Routines

These reduce the matrix A to a simpler form by a similarity transformation $S^{-1}AS=T$ where T is an upper Hessenberg or tridiagonal matrix, compute the eigensolutions of T, and then recover the eigenvectors of A via the matrix S. The eigenvectors are normalised so that

$$\sum_{r=1}^{n} |x_r|^2=1$$

x_r being the rth component of the eigenvector x, and so that the element of largest modulus is real if x is complex. For problems of the type Ax=(lambda)Bx with A and B symmetric and B positive-definite, the eigenvectors are normalised so that $x^TBx=1$, x always being real for such problems.

3.3. Singular Value and Singular Vector Routines

These reduce the matrix A to real bidiagonal form, B say, by orthogonal transformations $Q^T AP=B$ in the real case, and by unitary transformations $Q^H AP=B$ in the complex case, and the singular values and vectors are computed via this bidiagonal form. The singular values are returned in descending order.

3.4. Decision Trees

                  F02AAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F02AAF calculates all the eigenvalues of a real symmetric matrix.
```

```
2. Specification

       SUBROUTINE F02AAF (A, IA, N, R, E, IFAIL)
       INTEGER          IA, N, IFAIL
       DOUBLE PRECISION A(IA,N), R(N), E(N)

3. Description

This routine reduces the real symmetric matrix A to a real
symmetric tridiagonal matrix using Householder's method. The
eigenvalues of the tridiagonal matrix are then determined using
the QL algorithm.

4. References

[1]   Wilkinson J H and Reinsch C (1971) Handbook for Automatic
      Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

 1:  A(IA,N) -- DOUBLE PRECISION array               Input/Output
     On entry: the lower triangle of the n by n symmetric matrix
     A. The elements of the array above the diagonal need not be
     set. On exit: the elements of A below the diagonal are
     overwritten, and the rest of the array is unchanged.

 2:  IA -- INTEGER                                          Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which F02AAF is called.
     Constraint: IA >= N.

 3:  N -- INTEGER                                           Input
     On entry: n, the order of the matrix A.

 4:  R(N) -- DOUBLE PRECISION array                        Output
     On exit: the eigenvalues in ascending order.

 5:  E(N) -- DOUBLE PRECISION array                     Workspace

 6:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings
```

```
          Errors detected by the routine:

          IFAIL= 1
               Failure in F02AVF(*) indicating that more than 30*N
               iterations are required to isolate all the eigenvalues.

          7. Accuracy

          The accuracy of the eigenvalues depends on the sensitivity of the
          matrix to rounding errors produced in tridiagonalisation. For a
          detailed error analysis see Wilkinson and Reinsch [1] pp 222 and
          235.

          8. Further Comments

                                                                         3
          The time taken by the routine is approximately proportional to n

          9. Example

          To calculate all the eigenvalues of the real symmetric matrix:

                               ( 0.5  0.0  2.3 -2.6)
                               ( 0.0  0.5 -1.4 -0.7)
                               ( 2.3 -1.4  0.5  0.0).
                               (-2.6 -0.7  0.0  0.5)

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

F02ABF(3NAG)      Foundation Library (12/10/92)      F02ABF(3NAG)

     F02 -- Eigenvalue and Eigenvectors                          F02ABF
             F02ABF -- NAG Foundation Library Routine Document

     Note: Before using this routine, please read the Users' Note for
     your implementation to check implementation-dependent details.
     The symbol (*) after a NAG routine name denotes a routine that is
     not included in the Foundation Library.

     1. Purpose

     F02ABF calculates all the eigenvalues and eigenvectors of a real
     symmetric matrix.

     2. Specification

            SUBROUTINE F02ABF (A, IA, N, R, V, IV, E, IFAIL)
            INTEGER          IA, N, IV, IFAIL
            DOUBLE PRECISION A(IA,N), R(N), V(IV,N), E(N)

     3. Description

     This routine reduces the real symmetric matrix A to a real
     symmetric tridiagonal matrix by Householder's method. The
     eigenvalues and eigenvectors are calculated using the QL
     algorithm.

     4. References

     [1]   Wilkinson J H and Reinsch C (1971) Handbook for Automatic
           Computation II, Linear Algebra. Springer-Verlag.

     5. Parameters

      1:  A(IA,N) -- DOUBLE PRECISION array                      Input
          On entry: the lower triangle of the n by n symmetric matrix
          A. The elements of the array above the diagonal need not be
          set. See also Section 8.

      2:  IA -- INTEGER                                          Input
          On entry:
          the first dimension of the array A as declared in the
          (sub)program from which F02ABF is called.
          Constraint: IA >= N.

      3:  N -- INTEGER                                           Input
```

```
    On entry: n, the order of the matrix A.

 4: R(N) -- DOUBLE PRECISION array                       Output
    On exit: the eigenvalues in ascending order.

 5: V(IV,N) -- DOUBLE PRECISION array                    Output
    On exit: the normalised eigenvectors, stored by columns;
    the ith column corresponds to the ith eigenvalue. The
    eigenvectors are normalised so that the sum of squares of
    the elements is equal to 1.

 6: IV -- INTEGER                                         Input
    On entry:
    the first dimension of the array V as declared in the
    (sub)program from which F02ABF is called.
    Constraint: IV >= N.

 7: E(N) -- DOUBLE PRECISION array                    Workspace

 8: IFAIL -- INTEGER                               Input/Output
    On entry: IFAIL must be set to 0, -1 or 1. For users not
    familiar with this parameter (described in the Essential
    Introduction) the recommended value is 0.

    On exit: IFAIL = 0 unless the routine detects an error (see
    Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     Failure in F02AMF(*) indicating that more than 30*N
     iterations are required to isolate all the eigenvalues.

7. Accuracy

The eigenvectors are always accurately orthogonal but the
accuracy of the individual eigenvectors is dependent on their
inherent sensitivity to changes in the original matrix. For a
detailed error analysis see Wilkinson and Reinsch [1] pp 222 and
235.

8. Further Comments

                                                               3
The time taken by the routine is approximately proportional to n

Unless otherwise stated in the Users' Note for your
implementation, the routine may be called with the same actual
```

```
          array supplied for parameters A and V, in which case the
          eigenvectors will overwrite the original matrix. However this is
          not standard Fortran 77, and may not work on all systems.

          9. Example

          To calculate all the eigenvalues and eigenvectors of the real
          symmetric matrix:

                              ( 0.5  0.0  2.3 -2.6)
                              ( 0.0  0.5 -1.4 -0.7)
                              ( 2.3 -1.4  0.5  0.0).
                              (-2.6 -0.7  0.0  0.5)

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

16.5.16 Calculates all the eigenvalues of $Ax = \lambda Bx$

— nagf.ht —

```
\begin{page}{manpageXXf02adf}{NAG Documentation: f02adf}
\beginscroll
\begin{verbatim}

     F02ADF(3NAG)      Foundation Library (12/10/92)      F02ADF(3NAG)

          F02 -- Eigenvalue and Eigenvectors                         F02ADF
                  F02ADF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose
```

F02ADF calculates all the eigenvalues of Ax=(lambda)Bx, where A is a real symmetric matrix and B is a real symmetric positive-definite matrix.

2. Specification

```
       SUBROUTINE F02ADF (A, IA, B, IB, N, R, DE, IFAIL)
       INTEGER          IA, IB, N, IFAIL
       DOUBLE PRECISION A(IA,N), B(IB,N), R(N), DE(N)
```

3. Description

```
The problem is reduced to the standard symmetric eigenproblem
using Cholesky's method to decompose B into triangular matrices,
    T
B=LL , where L is lower triangular. Then Ax=(lambda)Bx implies
  -1  -T   T             T
(L  AL  )(L x)=(lambda)(L x); hence the eigenvalues of
Ax=(lambda)Bx are those of Py=(lambda)y where P is the symmetric
        -1  -T
matrix L  AL  . Householder's method is used to tridiagonalise
the matrix P and the eigenvalues are then found using the QL
algorithm.
```

4. References

[1]   Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

1: A(IA,N) -- DOUBLE PRECISION array   Input/Output
On entry: the upper triangle of the n by n symmetric matrix A. The elements of the array below the diagonal need not be set. On exit: the lower triangle of the array is overwritten. The rest of the array is unchanged.

2: IA -- INTEGER   Input
On entry:
the first dimension of the array A as declared in the (sub)program from which F02ADF is called.
Constraint: IA >= N.

3: B(IB,N) -- DOUBLE PRECISION array   Input/Output
On entry: the upper triangle of the n by n symmetric positive-definite matrix B. The elements of the array below the diagonal need not be set. On exit: the elements below the diagonal are overwritten. The rest of the array is unchanged.

```
 4:  IB -- INTEGER                                           Input
     On entry:
     the first dimension of the array B as declared in the
     (sub)program from which F02ADF is called.
     Constraint: IB >= N.

 5:  N -- INTEGER                                            Input
     On entry: n, the order of the matrices A and B.

 6:  R(N) -- DOUBLE PRECISION array                         Output
     On exit: the eigenvalues in ascending order.

 7:  DE(N) -- DOUBLE PRECISION array                     Workspace

 8:  IFAIL -- INTEGER                                 Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).
```

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     Failure in F01AEF(*); the matrix B is not positive-definite
     possibly due to rounding errors.

IFAIL= 2
     Failure in F02AVF(*), more than 30*N iterations are required
     to isolate all the eigenvalues.

7. Accuracy

In general this routine is very accurate. However, if B is ill-conditioned with respect to inversion, the eigenvalues could be inaccurately determined. For a detailed error analysis see Wilkinson and Reinsch [1] pp 310, 222 and 235.

8. Further Comments

The time taken by the routine is approximately proportional to n^3

9. Example

To calculate all the eigenvalues of the general symmetric

```
         eigenproblem Ax=(lambda) Bx where A is the symmetric matrix:

                                (0.5  1.5  6.6   4.8)
                                (1.5  6.5 16.2   8.6)
                                (6.6 16.2 37.6   9.8)
                                (4.8  8.6  9.8 -17.1)

         and B is the symmetric positive-definite matrix:

                                    (1  3  4  1)
                                    (3 13 16 11)
                                    (4 16 24 18).
                                    (1 11 18 27)

         The example program is not reproduced here. The source code for
         all example programs is distributed with the NAG Foundation
         Library software and should be available on-line.

                 F02AEF -- NAG Foundation Library Routine Document

         Note: Before using this routine, please read the Users' Note for
         your implementation to check implementation-dependent details.
         The symbol (*) after a NAG routine name denotes a routine that is
         not included in the Foundation Library.

         1. Purpose
```

F02AEF calculates all the eigenvalues and eigenvectors of Ax=(lambda)Bx, where A is a real symmetric matrix and B is a real symmetric positive-definite matrix.

2. Specification

```
       SUBROUTINE F02AEF (A, IA, B, IB, N, R, V, IV, DL, E, IFAIL)
       INTEGER          IA, IB, N, IV, IFAIL
       DOUBLE PRECISION A(IA,N), B(IB,N), R(N), V(IV,N), DL(N), E
      1                 (N)
```

3. Description

The problem is reduced to the standard symmetric eigenproblem using Cholesky's method to decompose B into triangular matrices $B=LL^T$, where L is lower triangular. Then Ax=(lambda)Bx implies $(L^{-1}AL^{-T})(L^Tx)=(\lambda)(L^Tx)$; hence the eigenvalues of Ax=(lambda)Bx are those of Py=(lambda)y, where P is the symmetric matrix $L^{-1}AL^{-T}$. Householder's method is used to tridiagonalise the matrix P and the eigenvalues are found using the QL algorithm. An eigenvector z of the derived problem is related to an eigenvector x of the original problem by $z=L^Tx$. The eigenvectors z are determined using the QL algorithm and are normalised so that $z^Tz=1$; the eigenvectors of the original problem are then determined by solving $L^Tx=z$, and are normalised so that $x^TBx=1$.

5. Parameters

1: A(IA,N) -- DOUBLE PRECISION array Input/Output

On entry: the upper triangle of the n by n symmetric matrix A. The elements of the array below the diagonal need not be set. On exit: the lower triangle of the array is overwritten. The rest of the array is unchanged. See also Section 8.

```
 2:  IA -- INTEGER                                     Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which F02AEF is called.
     Constraint: IA >= N.

 3:  B(IB,N) -- DOUBLE PRECISION array          Input/Output
     On entry: the upper triangle of the n by n symmetric
     positive-definite matrix B. The elements of the array below
     the diagonal need not be set. On exit: the elements below
     the diagonal are overwritten. The rest of the array is
     unchanged.

 4:  IB -- INTEGER                                     Input
     On entry:
     the first dimension of the array B as declared in the
     (sub)program from which F02AEF is called.
     Constraint: IB >= N.

 5:  N -- INTEGER                                      Input
     On entry: n, the order of the matrices A and B.

 6:  R(N) -- DOUBLE PRECISION array                   Output
     On exit: the eigenvalues in ascending order.

 7:  V(IV,N) -- DOUBLE PRECISION array                Output
     On exit: the normalised eigenvectors, stored by columns;
     the ith column corresponds to the ith eigenvalue. The
                                            T
     eigenvectors x are normalised so that x Bx=1. See also
     Section 8.

 8:  IV -- INTEGER                                     Input
     On entry:
     the first dimension of the array V as declared in the
     (sub)program from which F02AEF is called.
     Constraint: IV >= N.

 9:  DL(N) -- DOUBLE PRECISION array               Workspace

10:  E(N) -- DOUBLE PRECISION array                Workspace

11:  IFAIL -- INTEGER                           Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.
     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings
```

```
Errors detected by the routine:

IFAIL= 1
     Failure in F01AEF(*); the matrix B is not positive-definite,
     possibly due to rounding errors.

IFAIL= 2
     Failure in F02AMF(*); more than 30*N iterations are required
     to isolate all the eigenvalues.

7. Accuracy

In general this routine is very accurate. However, if B is ill-
conditioned with respect to inversion, the eigenvectors could be
inaccurately determined. For a detailed error analysis see
Wilkinson and Reinsch [1] pp 310, 222 and 235.

8. Further Comments

                                                                 3
The time taken by the routine is approximately proportional to n

Unless otherwise stated in the Users' Note for your
implementation, the routine may be called with the same actual
array supplied for parameters A and V, in which case the
eigenvectors will overwrite the original matrix A. However this
is not standard Fortran 77, and may not work on all systems.

9. Example

To calculate all the eigenvalues and eigenvectors of the general
symmetric eigenproblem Ax=(lambda) Bx where A is the symmetric
matrix:

                      (0.5  1.5  6.6   4.8)
                      (1.5  6.5 16.2   8.6)
                      (6.6 16.2 37.6   9.8)
                      (4.8  8.6  9.8 -17.1)

and B is the symmetric positive-definite matrix:

                          (1  3  4  1)
                          (3 13 16 11)
                          (4 16 24 18).
                          (1 11 18 27)

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

\begin{verbatim}

     F02AFF(3NAG)      Foundation Library (12/10/92)      F02AFF(3NAG)

          F02 -- Eigenvalue and Eigenvectors                         F02AFF
                  F02AFF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F02AFF calculates all the eigenvalues of a real unsymmetric
          matrix.

          2. Specification

                 SUBROUTINE F02AFF (A, IA, N, RR, RI, INTGER, IFAIL)
                 INTEGER          IA, N, INTGER(N), IFAIL
                 DOUBLE PRECISION A(IA,N), RR(N), RI(N)

          3. Description

          The matrix A is first balanced and then reduced to upper
          Hessenberg form using stabilised elementary similarity
          transformations. The eigenvalues are then found using the QR
          algorithm for real Hessenberg matrices.
```

```
4. References

      Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

 1:  A(IA,N) -- DOUBLE PRECISION array               Input/Output
     On entry: the n by n matrix A. On exit: the array is
     overwritten.

 2:  IA -- INTEGER                                          Input
     On entry:
     the dimension of the array A as declared in the (sub)program
     from which F02AFF is called.
     Constraint: IA >= N.

 3:  N -- INTEGER                                           Input
     On entry: n, the order of the matrix A.

 4:  RR(N) -- DOUBLE PRECISION array                       Output
     On exit: the real parts of the eigenvalues.

 5:  RI(N) -- DOUBLE PRECISION array                       Output
     On exit: the imaginary parts of the eigenvalues.

 6:  INTGER(N) -- INTEGER array                            Output
     On exit: INTGER(i) contains the number of iterations used
     to find the ith eigenvalue. If INTGER(i) is negative, the i
     th eigenvalue is the second of a pair found simultaneously.

     Note that the eigenvalues are found in reverse order,
     starting with the nth.

 7:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     More than 30*N iterations are required to isolate all the
     eigenvalues.
```

```
         7. Accuracy

         The accuracy of the results depends on the original matrix and
         the multiplicity of the roots. For a detailed error analysis see
         Wilkinson and Reinsch [1] pp 352 and 367.

         8. Further Comments

                                                                      3
         The time taken by the routine is approximately proportional to n

         9. Example

         To calculate all the eigenvalues of the real matrix:

                              (  1.5 0.1  4.5 -1.5)
                              (-22.5 3.5 12.5 -2.5)
                              ( -2.5 0.3  4.5 -2.5).
                              ( -2.5 0.1  4.5  2.5)

         The example program is not reproduced here. The source code for
         all example programs is distributed with the NAG Foundation
         Library software and should be available on-line.

16.5.19 Eigenvalues and eigenvectors of a real unsymmetric matrix

— nagf.ht —

```
\begin{page}{manpageXXf02agf}{NAG Documentation: f02agf}
\beginscroll
\begin{verbatim}

     F02AGF(3NAG)      Foundation Library (12/10/92)      F02AGF(3NAG)

         F02 -- Eigenvalue and Eigenvectors                        F02AGF
                 F02AGF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

F02AGF calculates all the eigenvalues and eigenvectors of a real
unsymmetric matrix.

2. Specification

```
       SUBROUTINE F02AGF (A, IA, N, RR, RI, VR, IVR, VI, IVI,
      1                   INTGER, IFAIL)
       INTEGER          IA, N, IVR, IVI, INTGER(N), IFAIL
       DOUBLE PRECISION A(IA,N), RR(N), RI(N), VR(IVR,N), VI
      1                 (IVI,N)
```

3. Description

The matrix A is first balanced and then reduced to upper
Hessenberg form using real stabilised elementary similarity
transformations. The eigenvalues and eigenvectors of the
Hessenberg matrix are calculated using the QR algorithm. The
eigenvectors of the Hessenberg matrix are back-transformed to
give the eigenvectors of the original matrix A.

4. References

[1]   Wilkinson J H and Reinsch C (1971) Handbook for Automatic
      Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

```
 1:  A(IA,N) -- DOUBLE PRECISION array               Input/Output
     On entry: the n by n matrix A. On exit: the array is
     overwritten.

 2:  IA -- INTEGER                                          Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which F02AGF is called.
     Constraint: IA >= N.

 3:  N -- INTEGER                                           Input
     On entry: n, the order of the matrix A.

 4:  RR(N) -- DOUBLE PRECISION array                       Output
     On exit: the real parts of the eigenvalues.
 5:  RI(N) -- DOUBLE PRECISION array                       Output
     On exit: the imaginary parts of the eigenvalues.

 6:  VR(IVR,N) -- DOUBLE PRECISION array                   Output
     On exit: the real parts of the eigenvectors, stored by
     columns. The ith column corresponds to the ith eigenvalue.
     The eigenvectors are normalised so that the sum of the
     squares of the moduli of the elements is equal to 1 and the
     element of largest modulus is real. This ensures that real
     eigenvalues have real eigenvectors.

 7:  IVR -- INTEGER                                         Input
     On entry:
     the first dimension of the array VR as declared in the
     (sub)program from which F02AGF is called.
     Constraint: IVR >= N.

 8:  VI(IVI,N) -- DOUBLE PRECISION array                   Output
     On exit: the imaginary parts of the eigenvectors, stored by
     columns. The ith column corresponds to the ith eigenvalue.

 9:  IVI -- INTEGER                                         Input
     On entry:
     the first dimension of the array VI as declared in the
     (sub)program from which F02AGF is called.
     Constraint: IVI >= N.

10:  INTGER(N) -- INTEGER array                            Output
     On exit: INTGER(i) contains the number of iterations used
     to find the ith eigenvalue. If INTGER(i) is negative, the i
     th eigenvalue is the second of a pair found simultaneously.

     Note that the eigenvalues are found in reverse order,
     starting with the nth.

11:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     More than 30*N iterations are required to isolate all the
     eigenvalues.
```

```
          7. Accuracy

          The accuracy of the results depends on the original matrix and
          the multiplicity of the roots. For a detailed error analysis see
          Wilkinson and Reinsch [1] pp 352 and 390.

          8. Further Comments

                                                                      3
          The time taken by the routine is approximately proportional to n

          9. Example

          To calculate all the eigenvalues and eigenvectors of the real
          matrix:

                                    (  1.5 0.1  4.5 -1.5)
                                    (-22.5 3.5 12.5 -2.5)
                                    ( -2.5 0.3  4.5 -2.5).
                                    ( -2.5 0.1  4.5  2.5)

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

```

```
        F02AJF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

F02AJF calculates all the eigenvalues of a complex matrix.

2. Specification

       SUBROUTINE F02AJF (AR, IAR, AI, IAI, N, RR, RI, INTGER,
      1                   IFAIL)
       INTEGER          IAR, IAI, N, INTGER(N), IFAIL
       DOUBLE PRECISION AR(IAR,N), AI(IAI,N), RR(N), RI(N)

3. Description

The complex matrix A is first balanced and then reduced to upper
Hessenberg form using stabilised elementary similarity
transformations. The eigenvalues are then found using the
modified LR algorithm for complex Hessenberg matrices.

4. References

[1]   Wilkinson J H and Reinsch C (1971) Handbook for Automatic
      Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

 1:  AR(IAR,N) -- DOUBLE PRECISION array             Input/Output
     On entry: the real parts of the elements of the n by n
     complex matrix A. On exit: the array is overwritten.

 2:  IAR -- INTEGER                                         Input
     On entry:
     the first dimension of the array AR as declared in the
     (sub)program from which F02AJF is called.
     Constraint: IAR >= N.

 3:  AI(IAI,N) -- DOUBLE PRECISION array             Input/Output
     On entry: the imaginary parts of the elements of the n by n
     complex matrix A. On exit: the array is overwritten.

 4:  IAI -- INTEGER                                         Input
     On entry:
     the first dimension of the array AI as declared in the
     (sub)program from which F02AJF is called.
```

```
    Constraint: IAI >= N.

 5:  N -- INTEGER                                         Input
     On entry: n, the order of the matrix A.

 6:  RR(N) -- DOUBLE PRECISION array                     Output
     On exit: the real parts of the eigenvalues.

 7:  RI(N) -- DOUBLE PRECISION array                     Output
     On exit: the imaginary parts of the eigenvalues.

 8:  INTGER(N) -- INTEGER array                       Workspace

 9:  IFAIL -- INTEGER                              Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     More than 30*N iterations are required to isolate all the
     eigenvalues.

7. Accuracy

The accuracy of the results depends on the original matrix and
the multiplicity of the roots. For a detailed error analysis see
Wilkinson and Reinsch [1] pp 352 and 401.

8. Further Comments

                                                                3
The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues of the complex matrix:

           (-21.0-5.0i      24.60i 13.6+10.2i     4.0i)
           (     22.5i 26.00-5.00i  7.5-10.0i 2.5     )
           ( -2.0+1.5i  1.68+2.24i  4.5-5.0i  1.5+2.0i).
           (     -2.5i -2.60       -2.7+3.6i  2.5-5.0i)

The example program is not reproduced here. The source code for
```

```
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

16.5.22 Eigenvalues of a complex Hermitian matrix

— nagf.ht —

```
\begin{page}{manpageXXf02awf}{NAG Documentation: f02awf}
\beginscroll
\begin{verbatim}

     F02AWF(3NAG)      Foundation Library (12/10/92)      F02AWF(3NAG)

          F02 -- Eigenvalue and Eigenvectors                       F02AWF
                  F02AWF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F02AWF calculates all the eigenvalues of a complex Hermitian
          matrix.

          2. Specification

                 SUBROUTINE F02AWF (AR, IAR, AI, IAI, N, R, WK1, WK2, WK3,
                1                   IFAIL)
                 INTEGER          IAR, IAI, N, IFAIL
                 DOUBLE PRECISION AR(IAR,N), AI(IAI,N), R(N), WK1(N),
      1                 WK2(N), WK3(N)
```

3. Description

The complex Hermitian matrix A is first reduced to a real tridiagonal matrix by n-2 unitary transformations, and a subsequent diagonal transformation. The eigenvalues are then derived using the QL algorithm, an adaptation of the QR algorithm.

4. References

[1]   Peters G (1967) NPL Algorithms Library. Document No. F1/04/A.

5. Parameters

```
 1:  AR(IAR,N) -- DOUBLE PRECISION array             Input/Output
     On entry: the real parts of the elements of the lower
     triangle of the n by n complex Hermitian matrix A. Elements
     of the array above the diagonal need not be set. On exit:
     the array is overwritten.

 2:  IAR -- INTEGER                                         Input
     On entry:
     the first dimension of the array AR as declared in the
     (sub)program from which F02AWF is called.
     Constraint: IAR >= N.

 3:  AI(IAI,N) -- DOUBLE PRECISION array             Input/Output
     On entry: the imaginary parts of the elements of the lower
     triangle of the n by n complex Hermitian matrix A. Elements
     of the array above the diagonal need not be set. On exit:
     the array is overwritten.

 4:  IAI -- INTEGER                                         Input
     On entry:
     the first dimension of the array AI as declared in the
     (sub)program from which F02AWF is called.
     Constraint: IAI >= N.

 5:  N -- INTEGER                                           Input
     On entry: n, the order of the complex Hermitian matrix, A.

 6:  R(N) -- DOUBLE PRECISION array                        Output
     On exit: the eigenvalues in ascending order.
 7:  WK1(N) -- DOUBLE PRECISION array                   Workspace

 8:  WK2(N) -- DOUBLE PRECISION array                   Workspace

 9:  WK3(N) -- DOUBLE PRECISION array                   Workspace

10:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     More than 30*N iterations are required to isolate all the
     eigenvalues.

7. Accuracy

For a detailed error analysis see Peters [1] page 3 and Wilkinson
and Reinsch [2] page 235.

8. Further Comments

                                                                3
The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues of the complex Hermitian matrix:

            (0.50        0.00       1.84+1.38i  2.08-1.56i)
            (0.00        0.50       1.12+0.84i -0.56+0.42i)
            (1.84-1.38i  1.12-0.84i 0.50        0.00      ).
            (2.08+1.56i -0.56-0.42i 0.00        0.50      )

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

16.5.23 Eigenvalues/eigenvectors complex Hermitian matrix

— **nagf.ht** —

```
\begin{page}{manpageXXf02axf}{NAG Documentation: f02axf}
\beginscroll
\begin{verbatim}

     F02AXF(3NAG)      Foundation Library (12/10/92)      F02AXF(3NAG)

          F02 -- Eigenvalue and Eigenvectors                         F02AXF
                  F02AXF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F02AXF calculates all the eigenvalues and eigenvectors of a
          complex Hermitian matrix.

          2. Specification

                 SUBROUTINE F02AXF (AR, IAR, AI, IAI, N, R, VR, IVR, VI,
                1                   IVI, WK1, WK2, WK3, IFAIL)
                 INTEGER          IAR, IAI, N, IVR, IVI, IFAIL
                 DOUBLE PRECISION AR(IAR,N), AI(IAI,N), R(N), VR(IVR,N), VI
                1                 (IVI,N), WK1(N), WK2(N), WK3(N)

          3. Description

          The complex Hermitian matrix is first reduced to a real
          tridiagonal matrix by n-2 unitary transformations and a
          subsequent diagonal transformation. The eigenvalues and
          eigenvectors are then derived using the QL algorithm, an
          adaptation of the QR algorithm.

          4. References

[2]   Peters G (1967) NPL Algorithms Library. Document No.
      F1/04/A.

5. Parameters

 1:  AR(IAR,N) -- DOUBLE PRECISION array                    Input
     On entry: the real parts of the elements of the lower
     triangle of the n by n complex Hermitian matrix A. Elements
     of the array above the diagonal need not be set. See also
     Section 8.

 2:  IAR -- INTEGER                                         Input
     On entry:
     the first dimension of the array AR as declared in the
     (sub)program from which F02AXF is called.
     Constraint: IAR >= N.

 3:  AI(IAI,N) -- DOUBLE PRECISION array                    Input
     On entry: the imaginary parts of the elements of the lower
     triangle of the n by n complex Hermitian matrix A. Elements
     of the array above the diagonal need not be set. See also
     Section 8.

 4:  IAI -- INTEGER                                         Input
     On entry:
     the first dimension of the array AI as declared in the
     (sub)program from which F02AXF is called.
     Constraint: IAI >= N.

 5:  N -- INTEGER                                           Input
     On entry: n, the order of the matrix, A.

 6:  R(N) -- DOUBLE PRECISION array                        Output
     On exit: the eigenvalues in ascending order.

 7:  VR(IVR,N) -- DOUBLE PRECISION array                   Output
     On exit: the real parts of the eigenvectors, stored by
     columns. The ith column corresponds to the ith eigenvector.
     The eigenvectors are normalised so that the sum of the
     squares of the moduli of the elements is equal to 1 and the
     element of largest modulus is real. See also Section 8.

 8:  IVR -- INTEGER                                         Input
     On entry:
     the first dimension of the array VR as declared in the
     (sub)program from which F02AXF is called.
     Constraint: IVR >= N.
 9:  VI(IVI,N) -- DOUBLE PRECISION array                   Output
     On exit: the imaginary parts of the eigenvectors, stored by
     columns. The ith column corresponds to the ith eigenvector.
     See also Section 8.

10:  IVI -- INTEGER                                         Input
     On entry:
     the first dimension of the array VI as declared in the
     (sub)program from which F02AXF is called.
     Constraint: IVI >= N.

11:  WK1(N) -- DOUBLE PRECISION array                   Workspace

12:  WK2(N) -- DOUBLE PRECISION array                   Workspace

13:  WK3(N) -- DOUBLE PRECISION array                   Workspace

14:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     More than 30*N iterations are required to isolate all the
     eigenvalues.

IFAIL= 2
     The diagonal elements of AI are not all zero, i.e., the
     complex matrix is not Hermitian.

7. Accuracy

The eigenvectors are always accurately orthogonal but the
accuracy of the individual eigenvalues and eigenvectors is
dependent on their inherent sensitivity to small changes in the
original matrix. For a detailed error analysis see Peters [1]
page 3 and [2] page 3.

8. Further Comments

                                                                3
The time taken by the routine is approximately proportional to n
```

```
          Unless otherwise stated in the implementation document, the
          routine may be called with the same actual array supplied for
          parameters AR and VR, and for AI and VI, in which case the
          eigenvectors will overwrite the original matrix A. However this
          is not standard Fortran 77, and may not work on all systems.

          9. Example

          To calculate the eigenvalues and eigenvectors of the complex
          Hermitian matrix:

                       (0.50        0.00       1.84+1.38i  2.08-1.56i)
                       (0.00        0.50       1.12+0.84i -0.56+0.42i)
                       (1.84-1.38i  1.12-0.84i 0.50        0.00      ).
                       (2.08+1.56i -0.56-0.42i 0.00        0.50      )

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

16.5.24 Eigenvalues and eigenvectors of a real symmetric matrix

— nagf.ht —

```
\begin{page}{manpageXXf02bbf}{NAG Documentation: f02bbf}
\beginscroll
\begin{verbatim}

     F02BBF(3NAG)      Foundation Library (12/10/92)      F02BBF(3NAG)

          F02 -- Eigenvalue and Eigenvectors                         F02BBF
                  F02BBF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.
```

1. Purpose

F02BBF calculates selected eigenvalues and eigenvectors of a real symmetric matrix by reduction to tridiagonal form, bisection and inverse iteration, where the selected eigenvalues lie within a given interval.

2. Specification

```
       SUBROUTINE F02BBF (A, IA, N, ALB, UB, M, MM, R, V, IV, D,
      1                   E, E2, X, G, C, ICOUNT, IFAIL)
       INTEGER          IA, N, M, MM, IV, ICOUNT(M), IFAIL
       DOUBLE PRECISION A(IA,N), ALB, UB, R(M), V(IV,M), D(N), E
      1                 (N), E2(N), X(N,7), G(N)
       LOGICAL          C(N)
```

3. Description

The real symmetric matrix A is reduced to a symmetric tridiagonal matrix T by Householder's method. The eigenvalues which lie within a given interval [l,u], are calculated by the method of bisection. The corresponding eigenvectors of T are calculated by inverse iteration. A back-transformation is then performed to obtain the eigenvectors of the original matrix A.

4. References

[1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

1: A(IA,N) -- DOUBLE PRECISION array Input/Output
On entry: the lower triangle of the n by n symmetric matrix A. The elements of the array above the diagonal need not be set. On exit: the elements of A below the diagonal are overwritten, and the rest of the array is unchanged.

2: IA -- INTEGER Input
On entry:
the first dimension of the array A as declared in the (sub)program from which F02BBF is called.
Constraint: IA >= N.

3: N -- INTEGER Input
On entry: n, the order of the matrix A.

4: ALB -- DOUBLE PRECISION Input

```
 5:  UB -- DOUBLE PRECISION                                Input
     On entry: l and u, the lower and upper end-points of the
     interval within which eigenvalues are to be calculated.

 6:  M -- INTEGER                                          Input
     On entry: an upper bound for the number of eigenvalues
     within the interval.

 7:  MM -- INTEGER                                        Output
     On exit: the actual number of eigenvalues within the
     interval.

 8:  R(M) -- DOUBLE PRECISION array                       Output
     On exit: the eigenvalues, not necessarily in ascending
     order.

 9:  V(IV,M) -- DOUBLE PRECISION array                    Output
     On exit: the eigenvectors, stored by columns. The ith
     column corresponds to the ith eigenvalue. The eigenvectors
     are normalised so that the sum of the squares of the
     elements are equal to 1.

10:  IV -- INTEGER                                         Input
     On entry:
     the first dimension of the array V as declared in the
     (sub)program from which F02BBF is called.
     Constraint: IV >= N.

11:  D(N) -- DOUBLE PRECISION array                    Workspace

12:  E(N) -- DOUBLE PRECISION array                    Workspace

13:  E2(N) -- DOUBLE PRECISION array                   Workspace

14:  X(N,7) -- DOUBLE PRECISION array                  Workspace

15:  G(N) -- DOUBLE PRECISION array                    Workspace

16:  C(N) -- LOGICAL array                             Workspace

17:  ICOUNT(M) -- INTEGER array                           Output
     On exit: ICOUNT(i) contains the number of iterations for
     the ith eigenvalue.

18:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
               Section 6).

          6. Error Indicators and Warnings

          Errors detected by the routine:

          IFAIL= 1
               M is less than the number of eigenvalues in the given
               interval. On exit MM contains the number of eigenvalues in
               the interval. Rerun with this value for M.

          IFAIL= 2
               More than 5 iterations are required to determine any one
               eigenvector.

          7. Accuracy

          There is no guarantee of the accuracy of the eigenvectors as the
          results depend on the original matrix and the multiplicity of the
          roots. For a detailed error analysis see Wilkinson and Reinsch
          [1] pp 222 and 436.

          8. Further Comments

                                                                          3
          The time taken by the routine is approximately proportional to n

          This subroutine should only be used when less than 25% of the
          eigenvalues and the corresponding eigenvectors are required. Also
          this subroutine is less efficient with matrices which have
          multiple eigenvalues.

          9. Example

          To calculate the eigenvalues lying between -2.0 and 3.0, and the
          corresponding eigenvectors of the real symmetric matrix:

                              ( 0.5  0.0  2.3 -2.6)
                              ( 0.0  0.5 -1.4 -0.7)
                              ( 2.3 -1.4  0.5  0.0).
                              (-2.6 -0.7  0.0  0.5)

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.
\end{verbatim}
\endscroll
\end{page}
```

———-

16.5.25 Eigenvalues of generalized eigenproblem $Ax = \lambda Bx$

— nagf.ht —

```
\begin{page}{manpageXXf02bjf}{NAG Documentation: f02bjf}
\beginscroll
\begin{verbatim}

     F02BJF(3NAG)      Foundation Library (12/10/92)      F02BJF(3NAG)

          F02 -- Eigenvalue and Eigenvectors                         F02BJF
                  F02BJF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F02BJF calculates all the eigenvalues and, if required, all the
          eigenvectors of the generalized eigenproblem  Ax=(lambda)Bx
          where A and B are real, square matrices, using the QZ algorithm.

          2. Specification

                 SUBROUTINE F02BJF (N, A, IA, B, IB, EPS1, ALFR, ALFI,
                1                   BETA, MATV, V, IV, ITER, IFAIL)
                 INTEGER          N, IA, IB, IV, ITER(N), IFAIL
                 DOUBLE PRECISION A(IA,N), B(IB,N), EPS1, ALFR(N), ALFI(N),
                1                 BETA(N), V(IV,N)
                 LOGICAL          MATV

          3. Description

          All the eigenvalues and, if required, all the eigenvectors of the
          generalized eigenproblem Ax=(lambda)Bx where A and B are real,
          square matrices, are determined using the QZ algorithm. The QZ
          algorithm consists of 4 stages:

          (a)   A is reduced to upper Hessenberg form and at the same time
                B is reduced to upper triangular form.
```

(b) A is further reduced to quasi-triangular form while the triangular form of B is maintained.

(c) The quasi-triangular form of A is reduced to triangular form and the eigenvalues extracted. This routine does not actually produce the eigenvalues (lambda)_j, but instead returns (alpha)_j and (beta)_j such that

$$\text{(lambda)}_j=\text{(alpha)}_j/\text{(beta)}_j, \quad j=1,2,...,.n$$

The division by (beta)_j becomes the responsibility of the user's program, since (beta)_j may be zero indicating an infinite eigenvalue. Pairs of complex eigenvalues occur with $\text{(alpha)}_j/\text{(beta)}_j$ and $\text{(alpha)}_{j+1}/\text{(beta)}_{j+1}$ complex conjugates, even though (alpha)_j and (alpha)_{j+1} are not conjugate.

(d) If the eigenvectors are required (MATV = .TRUE.), they are obtained from the triangular matrices and then transformed back into the original co-ordinate system.

5. Parameters

1: N -- INTEGER Input
On entry: n, the order of the matrices A and B.

2: A(IA,N) -- DOUBLE PRECISION array Input/Output
On entry: the n by n matrix A. On exit: the array is overwritten.

```
 3:  IA -- INTEGER                                          Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which F02BJF is called.
     Constraint: IA >= N.

 4:  B(IB,N) -- DOUBLE PRECISION array               Input/Output
     On entry: the n by n matrix B. On exit: the array is
     overwritten.

 5:  IB -- INTEGER                                          Input
     On entry:
     the first dimension of the array B as declared in the
     (sub)program from which F02BJF is called.
     Constraint: IB >= N.

 6:  EPS1 -- DOUBLE PRECISION                               Input
     On entry: the tolerance used to determine negligible
     elements. If EPS1 > 0.0, an element will be considered
     negligible if it is less than EPS1 times the norm of its
     matrix. If EPS1 <= 0.0, machine precision is used in place
     of EPS1. A positive value of EPS1 may result in faster
     execution but less accurate results.

 7:  ALFR(N) -- DOUBLE PRECISION array                     Output

 8:  ALFI(N) -- DOUBLE PRECISION array                     Output
     On exit: the real and imaginary parts of (alpha) , for
                                                    j
     j=1,2,...,n.

 9:  BETA(N) -- DOUBLE PRECISION array                     Output
     On exit: (beta) , for j=1,2,...,n.
                    j

10:  MATV -- LOGICAL                                        Input
     On entry: MATV must be set .TRUE. if the eigenvectors are
     required, otherwise .FALSE..

11:  V(IV,N) -- DOUBLE PRECISION array                     Output
     On exit: if MATV = .TRUE., then
          (i)if the jth eigenvalue is real, the jth column of V
          contains its eigenvector;

          (ii) if the jth and (j+1)th eigenvalues form a complex
          pair, the jth and (j+1)th columns of V contain the
          real and imaginary parts of the eigenvector associated
          with the first eigenvalue of the pair. The conjugate
          of this vector is the eigenvector for the conjugate
          eigenvalue.
     Each eigenvector is normalised so that the component of
     largest modulus is real and the sum of squares of the moduli
     equal one.

     If MATV = .FALSE., V is not used.

12:  IV -- INTEGER                                         Input
     On entry:
     the first dimension of the array V as declared in the
     (sub)program from which F02BJF is called.
     Constraint: IV >= N.

13:  ITER(N) -- INTEGER array                             Output
     On exit: ITER(j) contains the number of iterations needed
     to obtain the jth eigenvalue. Note that the eigenvalues are
     obtained in reverse order, starting with the nth.

14:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= i
     More than 30*N iterations are required to determine all the
     diagonal 1 by 1 or 2 by 2 blocks of the quasi-triangular
     form in the second step of the QZ algorithm. IFAIL is set to
     the index i of the eigenvalue at which this failure occurs.
     If the soft failure option is used, (alpha)  and (beta)  are
                                                j          j
     correct for j=i+1,i+2,...,n, but V does not contain any
     correct eigenvectors.

7. Accuracy

The computed eigenvalues are always exact for a problem
(A+E)x=(lambda)(B+F)x where ||E||/||A|| and ||F||/||B||
are both of the order of max(EPS1,(epsilon)), EPS1 being defined
as in Section 5 and (epsilon) being the machine precision.

Note: interpretation of results obtained with the QZ algorithm
often requires a clear understanding of the effects of small
changes in the original data. These effects are reviewed in
Wilkinson [3], in relation to the significance of small values of
```

```
          (alpha)  and (beta) . It should be noted that if (alpha)  and
                 j           j                                  j
          (beta)  are both small for any j, it may be that no reliance can
                j
          be placed on any of the computed eigenvalues
          (lambda) =(alpha) /(beta) . The user is recommended to study [3]
                  i        i       i
          and, if in difficulty, to seek expert advice on determining the
          sensitivity of the eigenvalues to perturbations in the data.

          8. Further Comments

                                                                         3
          The time taken by the routine is approximately proportional to n
          and also depends on the value chosen for parameter EPS1.

          9. Example

          To find all the eigenvalues and eigenvectors of Ax=(lambda) Bx
          where

                                (3.9 12.5 -34.5 -0.5)
                                (4.3 21.5 -47.5  7.5)
                              A=(4.3 21.5 -43.5  3.5)
                                (4.4 26.0 -46.0  6.0)

          and

                                     (1 2 -3 1)
                                     (1 3 -5 4)
                                   B=(1 3 -4 3).
                                     (1 3 -4 4)

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

     F02FJF(3NAG)      Foundation Library (12/10/92)      F02FJF(3NAG)

          F02 -- Eigenvalue and Eigenvectors                        F02FJF
                  F02FJF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          To find eigenvalues and eigenvectors of a real sparse symmetric
          or generalized symmetric eigenvalue problem.

          2. Specification

                 SUBROUTINE F02FJF (N, M, K, NOITS, TOL, DOT, IMAGE, MONIT,
                1                   NOVECS, X, NRX, D, WORK, LWORK, RWORK,
                2                   LRWORK, IWORK, LIWORK, IFAIL)
                 INTEGER          N, M, K, NOITS, NOVECS, NRX, LWORK,
                1                 LRWORK, IWORK(LIWORK), LIWORK, IFAIL
                 DOUBLE PRECISION TOL, DOT, X(NRX,K), D(K), WORK(LWORK),
                1                 RWORK(LRWORK)
                 EXTERNAL         DOT, IMAGE, MONIT

          3. Description

          F02FJF finds the m eigenvalues of largest absolute value and the
          corresponding eigenvectors for the real eigenvalue problem

                                  Cx=(lambda)x                          (1)

          where C is an n by n matrix such that
```

$$BC=C^T B \qquad (2)$$

for a given positive-definite matrix B. C is said to be B-symmetric. Different specifications of C allow for the solution of a variety of eigenvalue problems. For example, when

$$C=A \text{ and } B=I \text{ where } A=A^T$$

the routine finds the m eigenvalues of largest absolute magnitude for the standard symmetric eigenvalue problem

$$Ax=(\lambda)x. \qquad (3)$$

The routine is intended for the case where A is sparse.

As a second example, when

$$C=B^{-1} A$$

where

$$A=A^T$$

the routine finds the m eigenvalues of largest absolute magnitude for the generalized symmetric eigenvalue problem

$$Ax=(\lambda)Bx. \qquad (4)$$

The routine is intended for the case where A and B are sparse.

The routine does not require C explicitly, but C is specified via a user-supplied routine IMAGE which, given an n element vector z, computes the image w given by

$$w=Cz.$$

For instance, in the above example, where $C=B^{-1} A$, routine IMAGE will need to solve the positive-definite system of equations Bw=Az for w.

To find the m eigenvalues of smallest absolute magnitude of (3) we can choose $C=A^{-1}$ and hence find the reciprocals of the required eigenvalues, so that IMAGE will need to solve Aw=z for $^{-1}$

w, and correspondingly for (4) we can choose C=A B and solve
Aw=Bz for w.

A table of examples of choice of IMAGE is given in Table 3.1. It
should be remembered that the routine also returns the
corresponding eigenvectors and that B is positive-definite.
Throughout A is assumed to be symmetric and, where necessary,
non-singularity is also assumed.

Eigenvalues Required	Problem		
	Ax=(lambda)x	(B=I)Ax=(lambda)Bx	ABx=(lambda)x
Largest	Compute w=Az	Solve Bw=Az	Compute w=ABz
Smallest (Find 1/(lambda))	Solve Aw=z	Solve Aw=Bz	Solve Av=z, Bw=(nu)
Furthest from (sigma) (Find (lambda)-(sigma))	Compute w=(A-(sigma)I)z	Solve Bw=(A-(sigma)B)z	Compute w=(AB-(sigma)I)z
Closest to (sigma) (Find 1/((lambda)-(sigma)))	Solve (A-(sigma)I)w=z	Solve (A-(sigma)B)w=Bz	Solve (AB-(sigma)I)w=z

Table 3.1
The Requirement of IMAGE for Various Problems

The matrix B also need not be supplied explicitly, but is
specified via a user-supplied routine DOT which, given n element
vectors z and w, computes the generalized dot product $w^T Bz$.

F02FJF is based upon routine SIMITZ (see Nikolai [1]), which is
itself a derivative of the Algol procedure ritzit (see
Rutishauser [4]), and uses the method of simultaneous (subspace)
iteration. (See Parlett [2] for description, analysis and advice
on the use of the method.)

The routine performs simultaneous iteration on k>m vectors.

Initial estimates to p<=k eigenvectors, corresponding to the p eigenvalues of C of largest absolute value, may be supplied by the user to F02FJF. When possible k should be chosen so that the kth eigenvalue is not too close to the m required eigenvalues, but if k is initially chosen too small then F02FJF may be re-entered, supplying approximations to the k eigenvectors found so far and with k then increased.

At each major iteration F02FJF solves an r by r (r<=k) eigenvalue sub-problem in order to obtain an approximation to the eigenvalues for which convergence has not yet occurred. This approximation is refined by Chebyshev acceleration.

5. Parameters

```
 1:  N -- INTEGER                                          Input
     On entry: n, the order of the matrix C. Constraint: N >= 1.

 2:  M -- INTEGER                                   Input/Output
     On entry: m, the number of eigenvalues required.
                                   '
     Constraint: M >= 1. On exit: m, the number of eigenvalues
     actually found. It is equal to m if IFAIL = 0 on exit, and
     is less than m if IFAIL = 2, 3 or 4. See Section 6 and
     Section 8 for further information.

 3:  K -- INTEGER                                          Input
     On entry: the number of simultaneous iteration vectors to be
     used. Too small a value of K may inhibit convergence, while
     a larger value of K incurs additional storage and additional
     work per iteration. Suggested value: K = M + 4 will often be
     a reasonable choice in the absence of better information.
     Constraint: M < K <= N.

 4:  NOITS -- INTEGER                               Input/Output
```

On entry: the maximum number of major iterations (eigenvalue sub-problems) to be performed. If NOITS <= 0, then the value 100 is used in place of NOITS. On exit: the number of iterations actually performed.

5: TOL -- DOUBLE PRECISION Input

On entry: a relative tolerance to be used in accepting eigenvalues and eigenvectors. If the eigenvalues are required to about t significant figures, then TOL should be set to about 10^{-t}. d_i is accepted as an eigenvalue as soon as two successive approximations to d_i differ by less than $(|\tilde{d}_i|*TOL)/10$, where $\tilde{d}_i$ is the latest aproximation to d_i. Once an eigenvalue has been accepted, then an eigenvector is accepted as soon as $(d_i f_i)/(d_i - d_k) < TOL$, where f_i is the normalised residual of the current approximation to the eigenvector (see Section 8 for further information). The values of the f_i and d_i can be printed from routine MONIT. If TOL is supplied outside the range ((epsilon), 1.0), where (epsilon) is the machine precision, then the value (epsilon) is used in place of TOL.

6: DOT -- DOUBLE PRECISION FUNCTION, supplied by the user. External Procedure

DOT must return the value $w^T Bz$ for given vectors w and z. For the standard eigenvalue problem, where B=I, DOT must return the dot product $w^T z$.

Its specification is:

```
       DOUBLE PRECISION FUNCTION DOT (IFLAG, N, Z, W,
      1                              RWORK, LRWORK,
      2                              IWORK, LIWORK)
       INTEGER          IFLAG, N, LRWORK, IWORK(LIWORK),
      1                 LIWORK
       DOUBLE PRECISION Z(N), W(N), RWORK(LRWORK)
```

1: IFLAG -- INTEGER Input/Output

On entry: IFLAG is always non-negative. On exit: IFLAG may be used as a flag to indicate a failure in the computation of $w^T Bz$. If IFLAG is negative on exit from

```
         DOT, then F02FJF will exit immediately with IFAIL set
         to IFLAG. Note that in this case DOT must still be
         assigned a value.

     2:  N -- INTEGER                                      Input
         On entry: the number of elements in the vectors z and w
         and the order of the matrix B.

     3:  Z(N) -- DOUBLE PRECISION array                    Input
                                            T
         On entry: the vector z for which w Bz is required.

     4:  W(N) -- DOUBLE PRECISION array                    Input
                                            T
         On entry: the vector w for which w Bz is required.

     5:  RWORK(LRWORK) -- DOUBLE PRECISION array  User Workspace

     6:  LRWORK -- INTEGER                                 Input

     7:  IWORK(LIWORK) -- INTEGER array           User Workspace

     8:  LIWORK -- INTEGER                                 Input
         DOT is called from F02FJF with the parameters RWORK,
         LRWORK, IWORK and LIWORK as supplied to F02FJF. The
         user is free to use the arrays RWORK and IWORK to
         supply information to DOT and to IMAGE as an
         alternative to using COMMON.
    DOT must be declared as EXTERNAL in the (sub)program
    from which F02FJF is called. Parameters denoted as
    Input must not be changed by this procedure.

7:  IMAGE -- SUBROUTINE, supplied by the user.
                                              External Procedure
    IMAGE must return the vector w=Cz for a given vector z.

    Its specification is:

           SUBROUTINE IMAGE (IFLAG, N, Z, W, RWORK, LRWORK,
          1                  IWORK, LIWORK)
           INTEGER          IFLAG, N, LRWORK, IWORK(LIWORK),
          1                 LIWORK
           DOUBLE PRECISION Z(N), W(N), RWORK(LRWORK)

     1:  IFLAG -- INTEGER                           Input/Output
         On entry: IFLAG is always non-negative. On exit: IFLAG
         may be used as a flag to indicate a failure in the
         computation of w. If IFLAG is negative on exit from
         IMAGE, then F02FJF will exit immediately with IFAIL set
         to IFLAG.

     2:  N -- INTEGER                                      Input
         On entry: n, the number of elements in the vectors w
         and z, and the order of the matrix C.

     3:  Z(N) -- DOUBLE PRECISION array                    Input
         On entry: the vector z for which Cz is required.

     4:  W(N) -- DOUBLE PRECISION array                   Output
         On exit: the vector w=Cz.

     5:  RWORK(LRWORK) -- DOUBLE PRECISION array  User Workspace

     6:  LRWORK -- INTEGER                                 Input

     7:  IWORK(LIWORK) -- INTEGER array           User Workspace

     8:  LIWORK -- INTEGER                                 Input
         IMAGE is called from F02FJF with the parameters RWORK,
         LRWORK, IWORK and LIWORK as supplied to F02FJF. The
         user is free to use the arrays RWORK and IWORK to
         supply information to IMAGE and DOT as an alternative
         to using COMMON.
     IMAGE must be declared as EXTERNAL in the (sub)program
     from which F02FJF is called. Parameters denoted as
     Input must not be changed by this procedure.

 8:  MONIT -- SUBROUTINE, supplied by the user.
                                              External Procedure
     MONIT is used to monitor the progress of F02FJF. MONIT may
     be the dummy subroutine F02FJZ if no monitoring is actually
     required. (F02FJZ is included in the NAG Foundation Library
     and so need not be supplied by the user. The routine name
     F02FJZ may be implementation dependent: see the Users' Note
     for your implementation for details.) MONIT is called after
     the solution of each eigenvalue sub-problem and also just
     prior to return from F02FJF. The parameters ISTATE and
     NEXTIT allow selective printing by MONIT.

     Its specification is:

            SUBROUTINE MONIT (ISTATE, NEXTIT, NEVALS,
           1                  NEVECS, K, F, D)
            INTEGER          ISTATE, NEXTIT, NEVALS, NEVECS,
           1                 K
            DOUBLE PRECISION F(K), D(K)
      1:  ISTATE -- INTEGER                                 Input
          On entry: ISTATE specifies the state of F02FJF and will
          have values as follows:
          ISTATE = 0
                No eigenvalue or eigenvector has just been
                accepted.

          ISTATE = 1
                One or more eigenvalues have been accepted since
                the last call to MONIT.

          ISTATE = 2
                One or more eigenvectors have been accepted since
                the last call to MONIT.

          ISTATE = 3
                One or more eigenvalues and eigenvectors have
                been accepted since the last call to MONIT.

          ISTATE = 4
                Return from F02FJF is about to occur.

      2:  NEXTIT -- INTEGER                                 Input
          On entry: the number of the next iteration.

      3:  NEVALS -- INTEGER                                 Input
          On entry: the number of eigenvalues accepted so far.

      4:  NEVECS -- INTEGER                                 Input
          On entry: the number of eigenvectors accepted so far.

      5:  K -- INTEGER                                      Input
          On entry: k, the number of simultaneous iteration
          vectors.

      6:  F(K) -- DOUBLE PRECISION array                    Input
          On entry: a vector of error quantities measuring the
          state of convergence of the simultaneous iteration
          vectors. See the parameter TOL of F02FJF above and
          Section 8 for further details. Each element of F is
          initially set to the value 4.0 and an element remains
          at 4.0 until the corresponding vector is tested.

      7:  D(K) -- DOUBLE PRECISION array                    Input
          On entry: D(i) contains the latest approximation to the
          absolute value of the ith eigenvalue of C.
     MONIT must be declared as EXTERNAL in the (sub)program
     from which F02FJF is called. Parameters denoted as
     Input must not be changed by this procedure.
```

```
 9:  NOVECS -- INTEGER                                      Input
     On entry: the number of approximate vectors that are being
     supplied in X. If NOVECS is outside the range (0,K), then
     the value 0 is used in place of NOVECS.

10:  X(NRX,K) -- DOUBLE PRECISION array              Input/Output
     On entry: if 0 < NOVECS <= K, the first NOVECS columns of X
     must contain approximations to the eigenvectors
     corresponding to the NOVECS eigenvalues of largest absolute
     value of C. Supplying approximate eigenvectors can be useful
     when reasonable approximations are known, or when the
     routine is being restarted with a larger value of K.
     Otherwise it is not necessary to supply approximate vectors,
     as simultaneous iteration vectors will be generated randomly
     by the routine. On exit: if IFAIL = 0, 2, 3 or 4, the first
     m' columns contain the eigenvectors corresponding to the
     eigenvalues returned in the first m' elements of D (see
     below); and the next k-m'-1 columns contain approximations
     to the eigenvectors corresponding to the approximate
     eigenvalues returned in the next k-m'-1 elements of D. Here
     m' is the value returned in M (see above), the number of
     eigenvalues actually found. The kth column is used as
     workspace.

11:  NRX -- INTEGER                                         Input
     On entry:
     the first dimension of the array X as declared in the
     (sub)program from which F02FJF is called.
     Constraint: NRX >= N.

12:  D(K) -- DOUBLE PRECISION array                        Output
     On exit: if IFAIL = 0, 2, 3 or 4, the first m' elements
     contain the first m' eigenvalues in decreasing order of
     magnitude; and the next k-m'-1 elements contain
     approximations to the next k-m'-1 eigenvalues. Here m' is
     the value returned in M (see above), the number of
     eigenvalues actually found. D(k) contains the value e where
     (-e,e) is the latest interval over which Chebyshev
     acceleration is performed.

13:  WORK(LWORK) -- DOUBLE PRECISION array              Workspace

14:  LWORK -- INTEGER                                       Input
     On entry: the length of the array WORK, as declared in the
     (sub)program from which F02FJF is called. Constraint:
     LWORK>=3*K+max(K*K,2*N).

15:  RWORK(LRWORK) -- DOUBLE PRECISION array       User Workspace
     RWORK is not used by F02FJF, but is passed directly to
     routines DOT and IMAGE and may be used to supply information
     to these routines.

16:  LRWORK -- INTEGER                                      Input
     On entry: the length of the array RWORK, as declared in the
     (sub)program from which F02FJF is called. Constraint: LRWORK
     >= 1.

17:  IWORK(LIWORK) -- INTEGER array               User Workspace
     IWORK is not used by F02FJF, but is passed directly to
     routines DOT and IMAGE and may be used to supply information
     to these routines.

18:  LIWORK -- INTEGER                                      Input
     On entry: the length of the array IWORK, as declared in the
     (sub)program from which F02FJF is called. Constraint: LIWORK
     >= 1.

19:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. Users who are
     unfamiliar with this parameter should refer to the Essential
     Introduction for details.

     On exit: IFAIL = 0 unless the routine detects an error or
     gives a warning (see Section 6).

     For this routine, because the values of output parameters
     may be useful even if IFAIL /=0 on exit, users are
     recommended to set IFAIL to -1 before entry. It is then
     essential to test the value of IFAIL on exit. To suppress
     the output of an error message when soft failure occurs, set
     IFAIL to 1.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

IFAIL< 0
     A negative value of IFAIL indicates an exit from F02FJF
     because the user has set IFLAG negative in DOT or IMAGE. The
     value of IFAIL will be the same as the user's setting of
     IFLAG.

IFAIL= 1
     On entry N < 1,

     or       M < 1,

     or       M >= K,
     or      K > N,

     or      NRX < N,

     or      LWORK <3*K+max(K*K*N),

     or      LRWORK < 1,

     or      LIWORK < 1.

IFAIL= 2
     Not all the requested eigenvalues and vectors have been
     obtained. Approximations to the rth eigenvalue are
     oscillating rapidly indicating that severe cancellation is
     occurring in the rth eigenvector and so M is returned as (r-
     1). A restart with a larger value of K may permit
     convergence.

IFAIL= 3
     Not all the requested eigenvalues and vectors have been
     obtained. The rate of convergence of the remaining
     eigenvectors suggests that more than NOITS iterations would
     be required and so the input value of M has been reduced. A
     restart with a larger value of K may permit convergence.

IFAIL= 4
     Not all the requested eigenvalues and vectors have been
     obtained. NOITS iterations have been performed. A restart,
     possibly with a larger value of K, may permit convergence.

IFAIL= 5
     This error is very unlikely to occur, but indicates that
     convergence of the eigenvalue sub-problem has not taken
     place. Restarting with a different set of approximate
     vectors may allow convergence. If this error occurs the user
     should check carefully that F02FJF is being called
     correctly.

7. Accuracy

Eigenvalues and eigenvectors will normally be computed to the
accuracy requested by the parameter TOL, but eigenvectors
corresponding to small or to close eigenvalues may not always be
computed to the accuracy requested by the parameter TOL. Use of
the routine MONIT to monitor acceptance of eigenvalues and
eigenvectors is recommended.

8. Further Comments

The time taken by the routine will be principally determined by
```

the time taken to solve the eigenvalue sub-problem and the time taken by the routines DOT and IMAGE. The time taken to solve an eigenvalue sub-problem is approximately proportional to nk^2. It is important to be aware that several calls to DOT and IMAGE may occur on each major iteration.

As can be seen from Table 3.1, many applications of F02FJF will require routine IMAGE to solve a system of linear equations. For example, to find the smallest eigenvalues of Ax=(lambda)Bx, IMAGE needs to solve equations of the form Aw=Bz for w and routines from Chapters F01 and F04 of the NAG Foundation Library will frequently be useful in this context. In particular, if A is a positive-definite variable band matrix, F04MCF may be used after A has been factorized by F01MCF. Thus factorization need be performed only once prior to calling F02FJF. An illustration of this type of use is given in the example program in Section 9.

An approximation $\tilde{d}_h$, to the ith eigenvalue, is accepted as soon as $\tilde{d}_h$ and the previous approximation differ by less than $|\tilde{d}_h|$*TOL/10. Eigenvectors are accepted in groups corresponding to clusters of eigenvalues that are equal, or nearly equal, in absolute value and that have already been accepted. If d_r is the last eigenvalue in such a group and we define the residual r_j as

$$r_j=Cx_j-y_r$$

where y_r is the projection of Cx_j, with respect to B, onto the space spanned by $x_1,x_2,...,x_r$ and x_j is the current approximation to the jth eigenvector, then the value f_i returned in MONIT is given by

$$f_i=\max||r_j||_B/||Cx_j||_B \qquad ||x||_B^2=x^TBx$$

and each vector in the group is accepted as an eigenvector if

$$(|d_r|f_r)/(|d_r|-e)<TOL$$

where e is the current approximation to $|\tilde{d}_k|$. The values of the f_i are systematically increased if the convergence criteria appear to be too strict. See Rutishauser [4] for further details.

The algorithm implemented by F02FJF differs slightly from SIMITZ (Nikolai [1]) in that the eigenvalue sub-problem is solved using the singular value decomposition of the upper triangular matrix R of the Gram-Schmidt factorization of Cx_r , rather than forming $R^T R$

9. Example

To find the four eigenvalues of smallest absolute value and corresponding eigenvectors for the generalized symmetric eigenvalue problem Ax=(lambda)Bx, where A and B are the 16 by 16 matrices

```
  (1 a     a                      )
  (a 1 a     a                    )
  (  a 1 a     a                  )
  (    a 1 a     a                )
  (a     a 1 a     a              )
  (  a     a 1 a     a            )
  (    a     a 1 a     a          )
  (      a     a 1 a     a        )
A=(        a     a 1 a     a      )
  (          a     a 1 a     a    )
  (            a     a 1 a     a  )
  (              a     a 1 a     a)
  (                a     a 1 a    )
  (                  a     a 1 a  )
  (                    a     a 1 a)
  (                      a     a 1)
```

where $a=-\frac{1}{4}$

```
  (1 b                            )
  (b 1 b                          )
  (  b 1 b                        )
  (    b 1 b                      )
  (      b 1 b                    )
```

```
                    (       b 1 b                  )
                    (         b 1 b                )
                  B=(           b 1 b              )
                    (             b 1 b            )
                    (               b 1 b          )
                    (                 b 1 b        )
                    (                   b 1 b      )
                    (                     b 1 b    )
                    (                       b 1 b  )
                    (                         b 1 b)

                   1
          where b=- -
                   2

          TOL is taken as 0.0001 and 6 iteration vectors are used. F01MAF
          is used to factorize the matrix A, prior to calling F02FJF, and
          F04MAF is used within IMAGE to solve the equations Aw=Bz for w.
          Details of the factorization of A are passed from F01MAF to
          F04MAF by means of the COMMON block BLOCK1.

          Output from MONIT occurs each time ISTATE is non-zero. Note that
          the required eigenvalues are the reciprocals of the eigenvalues
          returned by F02FJF.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

```

```
F02 -- Eigenvalue and Eigenvectors                         F02WEF
        F02WEF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02WEF returns all, or part, of the singular value decomposition of a general real matrix.

2. Specification

```
       SUBROUTINE F02WEF (M, N, A, LDA, NCOLB, B, LDB, WANTQ, Q,
      1                   LDQ, SV, WANTP, PT, LDPT, WORK, IFAIL)
       INTEGER          M, N, LDA, NCOLB, LDB, LDQ, LDPT, IFAIL
       DOUBLE PRECISION A(LDA,*), B(LDB,*), Q(LDQ,*), SV(*), PT
      1                 (LDPT,*), WORK(*)
       LOGICAL          WANTQ, WANTP
```

3. Description

The m by n matrix A is factorized as

$$A=QDP^T,$$

where

$$D=\begin{pmatrix}S\\0\end{pmatrix}, \quad m>n,$$

$$D=S, \quad m=n,$$

$$D=(S\ 0), \quad m<n,$$

Q is an m by m orthogonal matrix, P is an n by n orthogonal matrix and S is a min(m,n) by min(m,n) diagonal matrix with non-negative diagonal elements, $sv_1,sv_2,\ldots,sv_{\min(m,n)}$, ordered such that

$$sv_1>=sv_2>=\ldots>=sv_{\min(m,n)}>=0.$$

The first min(m,n) columns of Q are the left-hand singular vectors of A, the diagonal elements of S are the singular values of A and the first min(m,n) columns of P are the right-hand singular vectors of A.

Either or both of the left-hand and right-hand singular vectors of A may be requested and the matrix C given by

$$C=Q^T B,$$

where B is an m by ncolb given matrix, may also be requested.

The routine obtains the singular value decomposition by first reducing A to upper triangular form by means of Householder transformations, from the left when m>=n and from the right when m<n. The upper triangular form is then reduced to bidiagonal form by Givens plane rotations and finally the QR algorithm is used to obtain the singular value decomposition of the bidiagonal form.

Good background descriptions to the singular value decomposition are given in Dongarra et al [1], Hammarling [2] and Wilkinson [3] DSVDC.

Note that if K is any orthogonal diagonal matrix so that

$$KK^T=I,$$

(so that K has elements +1 or -1 on the diagonal)

then

$$A=(QK)D(PK)^T$$

is also a singular value decomposition of A.

5. Parameters

1: M -- INTEGER Input
On entry: the number of rows, m, of the matrix A.
Constraint: M >= 0.

When M = 0 then an immediate return is effected.

2: N -- INTEGER Input
On entry: the number of columns, n, of the matrix A.
Constraint: N >= 0.

When N = 0 then an immediate return is effected.

3: A(LDA,*) -- DOUBLE PRECISION array Input/Output
Note: the second dimension of the array A must be at least max(1,N).
On entry: the leading m by n part of the array A must contain the matrix A whose singular value decomposition is required. On exit: if M >= N and WANTQ = .TRUE., then the leading m by n part of A will contain the first n columns of the orthogonal matrix Q.

If M < N and WANTP = .TRUE., then the leading m by n part of A will contain the first m rows of the orthogonal matrix P^T.

If M >= N and WANTQ = .FALSE. and WANTP = .TRUE., then the leading n by n part of A will contain the first n rows of the orthogonal matrix P^T.

Otherwise the leading m by n part of A is used as internal workspace.

4: LDA -- INTEGER Input
On entry:
the first dimension of the array A as declared in the (sub)program from which F02WEF is called.
Constraint: LDA >= max(1,M).

5: NCOLB -- INTEGER Input
On entry: ncolb, the number of columns of the matrix B.
When NCOLB = 0 the array B is not referenced. Constraint: NCOLB >= 0.

6: B(LDB,*) -- DOUBLE PRECISION array Input/Output
Note: the second dimension of the array B must be at least max(1,ncolb) On entry: if NCOLB > 0, the leading m by ncolb part of the array B must contain the matrix to be transformed. On exit: B is overwritten by the m by ncolb

```
               T
     matrix  Q B.

 7:  LDB -- INTEGER                                        Input
     On entry:
     the first dimension of the array B as declared in the
     (sub)program from which F02WEF is called.
     Constraint: if NCOLB > 0 then LDB >= max(1,M).

 8:  WANTQ -- LOGICAL                                      Input
     On entry: WANTQ must be .TRUE., if the left-hand singular
     vectors are required. If WANTQ = .FALSE., then the array Q
     is not referenced.

 9:  Q(LDQ,*) -- DOUBLE PRECISION array                   Output
     Note: the second dimension of the array Q must be at least
     max(1,M).
     On exit: if M < N and WANTQ = .TRUE., the leading m by m
     part of the array Q will contain the orthogonal matrix Q.
     Otherwise the array Q is not referenced.

10:  LDQ -- INTEGER                                        Input
     On entry:
     the first dimension of the array Q as declared in the
     (sub)program from which F02WEF is called.
     Constraint: if M < N and WANTQ = .TRUE., LDQ >= max(1,M).

11:  SV(*) -- DOUBLE PRECISION array                      Output
     Note: the length of SV must be at least min(M,N). On exit:
     the min(M,N) diagonal elements of the matrix S.

12:  WANTP -- LOGICAL                                      Input
     On entry: WANTP must be .TRUE. if the right-hand singular
     vectors are required. If WANTP = .FALSE., then the array PT
     is not referenced.

13:  PT(LDPT,*) -- DOUBLE PRECISION array                 Output
     Note: the second dimension of the array PT must be at least
     max(1,N).
     On exit: if M >= N and WANTQ and WANTP are .TRUE., the
     leading n by n part of the array PT will contain the
                       T
     orthogonal matrix P . Otherwise the array PT is not
     referenced.

14:  LDPT -- INTEGER                                       Input
     On entry:
     the first dimension of the array PT as declared in the
     (sub)program from which F02WEF is called.
     Constraint: if M >= N and WANTQ and WANTP are .TRUE., LDPT
     >= max(1,N).

15:  WORK(*) -- DOUBLE PRECISION array                     Output
     Note: the length of WORK must be at least max(1,lwork),
     where lwork must be as given in the following table:

     M >= N
     WANTQ is .TRUE. and WANTP = .TRUE.
                      2
           lwork=max(N +5*(N-1),N+NCOLB,4)

     WANTQ = .TRUE. and WANTP = .FALSE.
                      2
           lwork=max(N +4*(N-1),N+NCOLB,4)

     WANTQ = .FALSE. and WANTP = .TRUE.
           lwork=max(3*(N-1),2) when NCOLB = 0

           lwork=max(5*(N-1),2) when NCOLB > 0

     WANTQ = .FALSE. and WANTP = .FALSE.
           lwork=max(2*(N-1),2) when NCOLB = 0

           lwork=max(3*(N-1),2) when NCOLB > 0

     M < N
     WANTQ = .TRUE. and WANTP = .TRUE.
                      2
           lwork=max(M +5*(M-1),2)

     WANTQ = .TRUE. and WANTP = .FALSE.
           lwork=max(3*(M-1),1)

     WANTQ = .FALSE. and WANTP = .TRUE.
                      2
           lwork=max(M +3*(M-1),2) when NCOLB = 0

                      2
           lwork=max(M +5*(M-1),2) when NCOLB > 0

     WANTQ = .FALSE. and WANTP = .FALSE.
           lwork=max(2*(M-1),1) when NCOLB = 0

           lwork=max(3*(M-1),1) when NCOLB > 0
     On exit: WORK(min(M,N)) contains the total number of
     iterations taken by the R algorithm.

     The rest of the array is used as workspace.

16:  IFAIL -- INTEGER                                Input/Output
```

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL=-1

One or more of the following conditions holds:

M < 0,

N < 0,

LDA < M,

NCOLB < 0,

LDB < M and NCOLB > 0,

LDQ < M and M < N and WANTQ = .TRUE.,

LDPT < N and M >= N and WANTQ = .TRUE., and WANTP = . TRUE..

IFAIL> 0

The QR algorithm has failed to converge in 50*min(m,n) iterations. In this case SV(1), SV(2),..., SV(IFAIL) may not have been found correctly and the remaining singular values may not be the smallest. The matrix A will nevertheless have been factorized as $A=QEP^T$, where the leading min(m,n) by min(m,n) part of E is a bidiagonal matrix with SV(1), SV(2), ..., SV(min(m,n)) as the diagonal elements and WORK(1), WORK (2),..., WORK(min(m,n)-1) as the super-diagonal elements.

This failure is not likely to occur.

7. Accuracy

The computed factors Q, D and P satisfy the relation

$$QDP^T=A+E,$$

```
where

                  ||E||<=c(epsilon)||A||,

(epsilon) being the machine precision, c is a modest function of
m and n and ||.|| denotes the spectral (two) norm. Note that
||A||=sv .
        1

8. Further Comments

Following the use of this routine the rank of A may be estimated
by a call to the INTEGER FUNCTION F06KLF(*). The statement:

       IRANK = F06KLF(MIN(M, N), SV, 1, TOL)

returns the value (k-1) in IRANK, where k is the smallest integer
for which SV(k)<tol*SV(1), where tol is the tolerance supplied in
TOL, so that IRANK is an estimate of the rank of S and thus also
of A. If TOL is supplied as negative then the machine precision
is used in place of TOL.

9. Example

9.1. Example 1

To find the singular value decomposition of the 5 by 3 matrix

                          (2.0  2.5  2.5)
                          (2.0  2.5  2.5)
                        A=(1.6 -0.4  2.8)
                          (2.0 -0.5  0.5)
                          (1.2 -0.3 -2.9)

                          T
together with the vector Q b for the vector

                              ( 1.1)
                              ( 0.9)
                            b=( 0.6)
                              ( 0.0)
                              (-0.8)

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

9.2. Example 2
```

```
          To find the singular value decomposition of the 3 by 5 matrix

                                (2.0 2.0  1.6  2.0  1.2)
                              A=(2.5 2.5 -0.4 -0.5 -0.3)
                                (2.5 2.5  2.8  0.5 -2.9)

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

     F02XEF(3NAG)      Foundation Library (12/10/92)      F02XEF(3NAG)

          F02 -- Eigenvalue and Eigenvectors                      F02XEF
                  F02XEF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F02XEF returns all, or part, of the singular value decomposition
          of a general complex matrix.

          2. Specification

                 SUBROUTINE F02XEF (M, N, A, LDA, NCOLB, B, LDB, WANTQ, Q,
                1                   LDQ, SV, WANTP, PH, LDPH, RWORK, CWORK,
                2                   IFAIL)
                 INTEGER                   M, N, LDA, NCOLB, LDB, LDQ, LDPH,
                1                          IFAIL
                 DOUBLE PRECISION          SV(*), RWORK(*)
                 COMPLEX(KIND=KIND(1.0D0)) A(LDA,*), B(LDB,*), Q(LDQ,*),
                1                          PH(LDPH,*), CWORK(*)
                 LOGICAL                   WANTQ, WANTP
```

3. Description

The m by n matrix A is factorized as

$$A=QDP^H,$$

where

$$D=\begin{pmatrix}S\\0\end{pmatrix} \qquad m>n,$$

$$D=S, \qquad m=n,$$

$$D=(S\ 0), \qquad m<n,$$

Q is an m by m unitary matrix, P is an n by n unitary matrix and S is a min(m,n) by min(m,n) diagonal matrix with real non-negative diagonal elements, $sv_1,sv_2,...,sv_{min(m,n)}$, ordered such that

$$sv_1>=sv_2>=...>=sv_{min(m,n)}>=0.$$

The first min(m,n) columns of Q are the left-hand singular vectors of A, the diagonal elements of S are the singular values of A and the first min(m,n) columns of P are the right-hand singular vectors of A.

Either or both of the left-hand and right-hand singular vectors of A may be requested and the matrix C given by

$$C=Q^H B,$$

where B is an m by ncolb given matrix, may also be requested.

The routine obtains the singular value decomposition by first reducing A to upper triangular form by means of Householder transformations, from the left when m>=n and from the right when m<n. The upper triangular form is then reduced to bidiagonal form

by Givens plane rotations and finally the QR algorithm is used to obtain the singular value decomposition of the bidiagonal form.

Good background descriptions to the singular value decomposition are given in Dongarra et al [1], Hammarling [2] and Wilkinson [3] ZSVDC.

Note that if K is any unitary diagonal matrix so that

$$KK^H=I,$$

then

$$A=(QK)D(PK)^H$$

is also a singular value decomposition of A.

5. Parameters

```
 1:  M -- INTEGER                                             Input
     On entry: the number of rows, m, of the matrix A.
     Constraint: M >= 0.

     When M = 0 then an immediate return is effected.

 2:  N -- INTEGER                                             Input
     On entry: the number of columns, n, of the matrix A.
     Constraint: N >= 0.

     When N = 0 then an immediate return is effected.

 3:  A(LDA,*) -- COMPLEX(KIND(1.0D)) array             Input/Output
     Note: the second dimension of the array A must be at least
     max(1,N).
     On entry: the leading m by n part of the array A must
     contain the matrix A whose singular value decomposition is
```

required. On exit: if M >= N and WANTQ = .TRUE., then the leading m by n part of A will contain the first n columns of the unitary matrix Q.
If M < N and WANTP = .TRUE., then the leading m by n part of A will contain the first m rows of the unitary matrix P^H. will contain the first m rows of the unitary matrix P If M >= N and WANTQ = .FALSE. and WANTP = .TRUE., then the leading n by n part of A will contain the first n rows of the unitary matrix P^H. Otherwise the leading m by n part of A is used as internal workspace.

4: LDA -- INTEGER Input
On entry:
the first dimension of the array A as declared in the (sub)program from which F02XEF is called.
Constraint: LDA >= max(1,M).

5: NCOLB -- INTEGER Input
On entry: ncolb, the number of columns of the matrix B. When NCOLB = 0 the array B is not referenced. Constraint: NCOLB >= 0.

6: B(LDB,*) -- COMPLEX(KIND(1.0D)) array Input/Output
Note: the second dimension of the array B must be at least max(1,NCOLB).
On entry: if NCOLB > 0, the leading m by ncolb part of the array B must contain the matrix to be transformed. On exit: B is overwritten by the m by ncolb matrix $Q^H B$.

7: LDB -- INTEGER Input
On entry:
the first dimension of the array B as declared in the (sub)program from which F02XEF is called.
Constraint: if NCOLB > 0, then LDB >= max(1,M).

8: WANTQ -- LOGICAL Input
On entry: WANTQ must be .TRUE. if the left-hand singular vectors are required. If WANTQ = .FALSE. then the array Q is not referenced.

9: Q(LDQ,*) -- COMPLEX(KIND(1.0D)) array Output
Note: the second dimension of the array Q must be at least max(1,M).
On exit: if M < N and WANTQ = .TRUE., the leading m by m part of the array Q will contain the unitary matrix Q. Otherwise the array Q is not referenced.

```
10:  LDQ -- INTEGER                                        Input
     On entry:
     the first dimension of the array Q as declared in the
     (sub)program from which F02XEF is called.
     Constraint: if M < N and WANTQ = .TRUE., LDQ >= max(1,M).

11:  SV(*) -- DOUBLE PRECISION array                      Output
     Note: the length of SV must be at least min(M,N). On exit:
     the min(m,n) diagonal elements of the matrix S.

12:  WANTP -- LOGICAL                                      Input
     On entry: WANTP must be .TRUE. if the right-hand singular
     vectors are required. If WANTP = .FALSE. then the array PH
     is not referenced.

13:  PH(LDPH,*) -- DOUBLE PRECISION array                 Output
     Note: the second dimension of the array PH must be at least
     max(1,N).
     On exit: if M >= N and WANTQ and WANTP are .TRUE., the
     leading n by n part of the array PH will contain the unitary
            H
     matrix P . Otherwise the array PH is not referenced.

14:  LDPH -- INTEGER                                       Input
     On entry:
     the first dimension of the array PH as declared in the
     (sub)program from which F02XEF is called.
     Constraint: if M >= N and WANTQ and WANTP are .TRUE.,  LDPH
     >= max(1,N).

15:  RWORK(*) -- DOUBLE PRECISION array                   Output
     Note: the length of RWORK must be at least max(1,lrwork),
     where lrwork must satisfy:
     lrwork=2*(min(M,N)-1) when
           NCOLB = 0 and WANTQ and WANTP are .FALSE.,

     lrwork=3*(min(M,N)-1) when
           either NCOLB = 0 and WANTQ = .FALSE. and WANTP = .
           TRUE., or WANTP = .FALSE. and one or both of NCOLB > 0
           and WANTQ = .TRUE.

     lrwork=5*(min(M,N)-1)
           otherwise.
     On exit: RWORK(min(M,N)) contains the total number of
     iterations taken by the QR algorithm.

     The rest of the array is used as workspace.

16:  CWORK(*) -- COMPLEX(KIND(1.0D)) array             Workspace
     Note: the length of CWORK must be at least max(1,lcwork),
     where lcwork must satisfy:
                   2
     lcwork=N+max(N ,NCOLB) when
           M >= N and WANTQ and WANTP are both .TRUE.

                   2
     lcwork=N+max(N +N,NCOLB) when
           M >= N and WANTQ = .TRUE., but WANTP = .FALSE.

     lcwork=N+max(N,NCOLB) when
           M >= N and WANTQ = .FALSE.

             2
     lcwork=M +M when
           M < N and WANTP = .TRUE.

     lcwork = M when
           M < N and WANTP = .FALSE.

17:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL=-1
     One or more of the following conditions holds:
          M < 0,

          N < 0,

          LDA < M,

          NCOLB < 0,

          LDB < M and NCOLB > 0,

          LDQ < M and M < N and WANTQ = .TRUE.,

          LDPH < N and M >= N and WANTQ = .TRUE. and WANTP = .
          TRUE..
```

IFAIL> 0

The QR algorithm has failed to converge in 50*min(m,n) iterations. In this case SV(1), SV(2),..., SV(IFAIL) may not have been found correctly and the remaining singular values may not be the smallest. The matrix A will nevertheless have been factorized as $A=QEP^H$ where the leading min(m,n) by min(m,n) part of E is a bidiagonal matrix with SV(1), SV(2), ..., SV(min(m,n)) as the diagonal elements and RWORK(1), RWORK(2),..., RWORK(min(m,n)-1) as the super-diagonal elements.

This failure is not likely to occur.

7. Accuracy

The computed factors Q, D and P satisfy the relation

$$QDP^H=A+E,$$

where

$$||E||<=c(\epsilon)||A||,$$

(epsilon) being the machine precision, c is a modest function of m and n and ||.|| denotes the spectral (two) norm. Note that $||A||=sv_1$.

8. Further Comments

Following the use of this routine the rank of A may be estimated by a call to the INTEGER FUNCTION F06KLF(*). The statement:

```
        IRANK = F06KLF(MIN(M, N), SV, 1, TOL)
```

returns the value (k-1) in IRANK, where k is the smallest integer for which SV(k)<tol*SV(1), where tol is the tolerance supplied in TOL, so that IRANK is an estimate of the rank of S and thus also of A. If TOL is supplied as negative then the machine precision is used in place of TOL.

9. Example

9.1. Example 1

To find the singular value decomposition of the 5 by 3 matrix

```
                              (    0.5i -0.5+1.5i -1.0+1.0i)
                              (0.4+0.3i  0.9+1.3i  0.2+1.4i)
                            A=(0.4      -0.4+0.4i  1.8     )
                              (0.3-0.4i  0.1+0.7i  0.0     )
                              (   -0.3i  0.3+0.3i      2.4i)

                                     H
          together with the vector Q b for the vector

                                      (-0.55+1.05i)
                                      ( 0.49+0.93i)
                                    b=( 0.56-0.16i)
                                      ( 0.39+0.23i)
                                      ( 1.13+0.83i)

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

          9.2. Example 2

          To find the singular value decompostition of the 3 by 5 matrix

                    (     0.5i 0.4-0.3i  0.4      0.3+0.4i     0.3i)
                  A=(-0.5-1.5i 0.9-1.3i -0.4-0.4i 0.1-0.7i 0.3-0.3i)
                    (-1.0-1.0i 0.2-1.4i  1.8      0.0         -2.4i)

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation

16.5.29 Simultaneous Linear Equations

— nagf.ht —

```
\begin{page}{manpageXXf04}{NAG Documentation: f04}
\beginscroll
\begin{verbatim}
```

Chapter F04
Simultaneous Linear Equations

1. Scope of the Chapter

This chapter, together with two routines in Chapter F07, is concerned with the solution of the matrix equation AX=B, where B may be a single vector or a matrix of multiple right-hand sides. The matrix A may be real, complex, symmetric, Hermitian positive-definite, or sparse. It may also be rectangular, in which case a least-squares solution is obtained.

2. Background to the Problems

A set of linear equations may be written in the form

$$Ax=b$$

where the known matrix A, with real or complex coefficients, is of size m by n, (m rows and n columns), the known right-hand vector b has m components (m rows and one column), and the required solution vector x has n components (n rows and one column). There may sometimes be p vectors b_i, i=1,2,...,p on the right-hand side and the equations may then be written as

$$AX=B$$

the required matrix X having as its p columns the solutions of $Ax_i=b_i$, i=1,2,...,p. Some routines deal with the latter case, but for clarity only the case p=1 is discussed here.

The most common problem, the determination of the unique solution of Ax=b, occurs when m=n and A is non-singular, that is rank(A)=n problem, discussed in Section 2.2 below, is the determination of the least-squares solution of Ax~=b, i.e., the determination of a vector x which minimizes the Euclidean length (two norm) of the residual vector r=b-Ax. The usual case has m>n and rank(A)=n, in which case x is unique.

2.1. Unique Solution of Ax=b

Most of the routines in this chapter, as well as two routines in

Chapter F07, solve this particular problem. The solution is obtained by performing either an LU factorization, or a Cholesky factorization, as discussed in Section 2 of the F01 Chapter Introduction.

Two of the routines in this chapter use a process called iterative refinement to improve the initial solution in order to obtain a solution that is correct to working accuracy. It should be emphasised that if A and b are not known exactly then not all the figures in this solution may be meaningful. To be more precise, if x is the exact solution of the equations

$$Ax=b$$

and x is the solution of the perturbed equations

$$(A+E)x=b+e,$$

then, provided that $(kappa)(A)\frac{||E||}{||A||}<=1$,

$$\frac{||x-x||}{||x||} <= \frac{(kappa)(A)}{1-(kappa)(A)\frac{||E||}{||A||}}\left(\frac{||E||}{||A||}+\frac{||e||}{||b||}\right),$$

where $(kappa)(A)=||A||||A^{-1}||$ is the condition number of A with respect to inversion. Thus, if A is ill-conditioned (

(kappa)(A) is large), x may differ significantly from x. Often $(kappa)(A)\frac{||E||}{||A||}<<1$ in which case the above bound effectively reduces to

```
          ||x-x||              ( ||E||   ||e|| )
```

```
            ------- <= (kappa)(A)( ----- + ----- ).
             ||x||               ( ||A||   ||b|| )
```

2.2. The Least-squares Solution of Ax~=b

The least-squares problem is to find a vector x to minimize

```
                          T
                         r r,  where r=b-Ax.
```

When m>=n and rank(A)=n then the solution vector x is unique. For the cases where x is not unique the routines in this chapter obtain the minimal length solution, that is the vector x for

```
       T
which x x is a minimum.
```

2.3. Calculating the Inverse of a Matrix

The routines in this chapter can also be used to calculate the inverse of a square matrix A by solving the equation

```
                              AX=I,
```

where I is the identity matrix.

3. Recommendations on Choice and Use of Routines

3.1. General Purpose Routines

Many of the routines in this chapter perform the complete solution of the required equations, but some of the routines, as well as the routines in Chapter F07, assume that a prior factorization has been performed, using the appropriate factorization routine from Chapter F01 or Chapter F07. These, so-called, general purpose routines can be useful when explicit information on the factorization is required, as well as the solution of the equations, or when the solution is required for multiple right-hand sides, or for a sequence of right-hand sides.

Note that some of the routines that perform a complete solution also allow multiple right-hand sides.

3.2. Iterative Refinement

The routines that perform iterative refinement are more costly than those that do not perform iterative refinement, both in terms of time and storage, and should only be used if the problem really warrants the additional accuracy provided by these routines. The storage requirements are approximately doubled, while the additional time is not usually prohibitive since the initial factorization is used at each iteration.

3.3. Sparse Matrix Routines

The routines for sparse matrices should usually be used only when the number of non-zero elements is very small, less than 10% of the total number of elements of A. Additionally, when the matrix is symmetric positive-definite the sparse routines should generally be used only when A does not have a (variable) band structure.

There are four routines for solving sparse linear equations, two for solving general real systems (F04AXF and F04QAF), one for solving symmetric positive-definite systems (F04MAF) and one for solving symmetric systems that may, or may not, be positive-definite (F04MBF). F04AXF and F04MAF utilise factorizations of the matrix A obtained by routines in Chapter F01, while the other two routines use iterative techniques and require a user-supplied function to compute matrix-vector products Ac and A^T c for any given vector c. The routines requiring factorizations will usually be faster and the factorization can be utilised to solve for several right-hand sides, but the original matrix has to be explicitly supplied and is overwritten by the factorization, and the storage requirements will usually be substantially more than those of the iterative routines.

Routines F04MBF and F04QAF both allow the user to supply a pre-conditioner.

F04MBF can be used to solve systems of the form (A-(lambda)I)x=b, which can be useful in applications such as Rayleigh quotient iteration.

F04QAF also solves sparse least-squares problems and allows the solution of damped (regularized) least-squares problems.

3.4. Decision Trees

If at any stage the answer to a question is 'Don't know' this should be read as 'No'.

For those routines that need to be preceded by a factorization routine, the appropriate routine name is given in brackets after the name of the routine for solving the equations. Note also that you may be directed to a routine in Chapter F07.

3.4.1. Routines for unique solution of Ax=b

     F04ADF(3NAG)      Foundation Library (12/10/92)      F04ADF(3NAG)

          F04 -- Simultaneous Linear Equations                       F04ADF
                  F04ADF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F04ADF calculates the approximate solution of a set of complex
          linear equations with multiple right-hand sides, using an LU
          factorization with partial pivoting.

          2. Specification

                 SUBROUTINE F04ADF (A, IA, B, IB, N, M, C, IC, WKSPCE,
                1                   IFAIL)
                 INTEGER             IA, IB, N, M, IC, IFAIL
                 DOUBLE PRECISION    WKSPCE(*)
                 COMPLEX(KIND(1.0D0)) A(IA,*), B(IB,*), C(IC,*)
```

```
3. Description

Given a set of complex linear equations AX=B, the routine first
computes an LU factorization of A with partial pivoting, PA=LU,
where P is a permutation matrix, L is lower triangular and U is
unit upper triangular. The columns x of the solution X are found
by forward and backward substitution in Ly=Pb and Ux=y, where b
is a column of the right-hand side matrix B.

4. References

[1]   Wilkinson J H and Reinsch C (1971) Handbook for Automatic
      Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

 1:  A(IA,*) -- COMPLEX(KIND(1.0D)) array            Input/Output
     Note: the second dimension of the array A must be at least
     max(1,N).
     On entry: the n by n matrix A. On exit: A is overwritten by
     the lower triangular matrix L and the off-diagonal elements
     of the upper triangular matrix U. The unit diagonal elements
     of U are not stored.

 2:  IA -- INTEGER                                          Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which F04ADF is called.
     Constraint: IA >= max(1,N).

 3:  B(IB,*) -- COMPLEX(KIND(1.0D)) array                   Input
     Note: the second dimension of the array B must be at least
     max(1,M).
     On entry: the n by m right-hand side matrix B. See also
     Section 8.

 4:  IB -- INTEGER                                          Input
     On entry:
     the first dimension of the array B as declared in the
     (sub)program from which F04ADF is called.
     Constraint: IB >= max(1,N).

 5:  N -- INTEGER                                           Input
     On entry: n, the order of the matrix A. Constraint: N >= 0.

 6:  M -- INTEGER                                           Input
     On entry: m, the number of right-hand sides. Constraint: M
     >= 0.

 7:  C(IC,*) -- COMPLEX(KIND(1.0D)) array                  Output
```

```
     Note: the second dimension of the array C must be at least
     max(1,M).
     On exit: the n by m solution matrix X. See also Section 8.

 8:  IC -- INTEGER                                          Input
     On entry:
     the first dimension of the array C as declared in the
     (sub)program from which F04ADF is called.
     Constraint: IC >= max(1,N).

 9:  WKSPCE(*) -- DOUBLE PRECISION array                Workspace
     Note: the dimension of the array WKSPCE must be at least
     max(1,N).

10:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     The matrix A is singular, possibly due to rounding errors.

IFAIL= 2
     On entry N < 0,

     or       M < 0,

     or       IA < max(1,N),

     or       IB < max(1,N),

     or       IC < max(1,N).

7. Accuracy

The accuracy of the computed solution depends on the conditioning
of the original matrix. For a detailed error analysis see
Wilkinson and Reinsch [1] page 106.

8. Further Comments
```

```
                                                             3
          The time taken by the routine is approximately proportional to n

          Unless otherwise stated in the Users' Note for your
          implementation, the routine may be called with the same actual
          array supplied for parameters B and C, in which case the solution
          vectors will overwrite the right-hand sides. However this is not
          standard Fortran 77, and may not work on all systems.

          9. Example

          To solve the set of linear equations AX=B where

                                    (1   1+2i  2+10i)
                                  A=(1+i  3i  -5+14i)
                                    (1+i  5i  -8+20i)

          and

                                          (1)
                                        B=(0).
                                          (0)

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

F04 -- Simultaneous Linear Equations                        F04ARF
        F04ARF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

F04ARF calculates the approximate solution of a set of real
linear equations with a single right-hand side, using an LU
factorization with partial pivoting.

2. Specification

       SUBROUTINE F04ARF (A, IA, B, N, C, WKSPCE, IFAIL)
       INTEGER          IA, N, IFAIL
       DOUBLE PRECISION A(IA,*), B(*), C(*), WKSPCE(*)

3. Description

Given a set of linear equations, Ax=b, the routine first computes
an LU factorization of A with partial pivoting, PA=LU, where P is
a permutation matrix, L is lower triangular and U is unit upper
triangular. The approximate solution x is found by forward and
backward substitution in Ly=Pb and Ux=y, where b is the right-
hand side.

4. References

[1]   Wilkinson J H and Reinsch C (1971) Handbook for Automatic
      Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

 1:  A(IA,*) -- DOUBLE PRECISION array               Input/Output
     Note: the second dimension of the array A must be at least
     max(1,N).
     On entry: the n by n matrix A. On exit: A is overwritten by
     the lower triangular matrix L and the off-diagonal elements
     of the upper triangular matrix U. The unit diagonal elements
     of U are not stored.

 2:  IA -- INTEGER                                          Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which F04ARF is called.
```

```
    Constraint: IA >= max(1,N).

 3:  B(*) -- DOUBLE PRECISION array                          Input
     Note: the dimension of the array B must be at least
     max(1,N).
     On entry: the right-hand side vector b.

 4:  N -- INTEGER                                            Input
     On entry: n, the order of the matrix A. Constraint: N >= 0.

 5:  C(*) -- DOUBLE PRECISION array                         Output
     Note: the dimension of the array C must be at least
     max(1,N).
     On exit: the solution vector x.

 6:  WKSPCE(*) -- DOUBLE PRECISION array                 Workspace
     Note: the dimension of the array WKSPCE must be at least
     max(1,N).

 7:  IFAIL -- INTEGER                                 Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     The matrix A is singular, possibly due to rounding errors.

IFAIL= 2
     On entry N < 0,

     or       IA < max(1,N).

7. Accuracy

The accuracy of the computed solution depends on the conditioning
of the original matrix. For a detailed error analysis see
Wilkinson and Reinsch [1] page 107.

8. Further Comments
```

```
                                                                   3
          The time taken by the routine is approximately proportional to n

          Unless otherwise stated in the Users' Note for your
          implementation, the routine may be called with the same actual
          array supplied for parameters B and C, in which case the solution
          vector will overwrite the right-hand side. However this is not
          standard Fortran 77, and may not work on all systems.

          9. Example

          To solve the set of linear equations Ax=b where

                                     ( 33  16  72)
                                   A=(-24 -10 -57)
                                     ( -8  -4 -17)

          and

                                        (-359)
                                      b=( 281).
                                        (  85)

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

```

F04 -- Simultaneous Linear Equations F04ASF

F04ASF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F04ASF calculates the accurate solution of a set of real symmetric positive-definite linear equations with a single right-hand side, $Ax=b$, using a Cholesky factorization and iterative refinement.

2. Specification

```
      SUBROUTINE F04ASF (A, IA, B, N, C, WK1, WK2, IFAIL)
      INTEGER          IA, N, IFAIL
      DOUBLE PRECISION A(IA,*), B(*), C(*), WK1(*), WK2(*)
```

3. Description

Given a set of real linear equations $Ax=b$, where A is a symmetric positive-definite matrix, the routine first computes a Cholesky factorization of A as $A=LL^T$ where L is lower triangular. An approximation to x is found by forward and backward substitution. The residual vector $r=b-Ax$ is then calculated using additional precision and a correction d to x is found by solving $LL^Td=r$. x is then replaced by $x+d$, and this iterative refinement of the solution is repeated until machine accuracy is obtained.

4. References

[1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

1: A(IA,*) -- DOUBLE PRECISION array Input/Output

Note: the second dimension of the array A must be at least max(1,N).

On entry: the upper triangle of the n by n positive-definite symmetric matrix A. The elements of the array below the diagonal need not be set. On exit: the elements of the array below the diagonal are overwritten; the upper triangle of A is unchanged.

```
 2:  IA -- INTEGER                                        Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which F04ASF is called.
     Constraint: IA >= max(1,N).

 3:  B(*) -- DOUBLE PRECISION array                       Input
     Note: the dimension of the array B must be at least
     max(1,N).
     On entry: the right-hand side vector b.

 4:  N -- INTEGER                                         Input
     On entry: n, the order of the matrix A. Constraint: N >= 0.

 5:  C(*) -- DOUBLE PRECISION array                      Output
     Note: the dimension of the array C must be at least
     max(1,N).
     On exit: the solution vector x.

 6:  WK1(*) -- DOUBLE PRECISION array                 Workspace
     Note: the dimension of the array WK1 must be at least
     max(1,N).

 7:  WK2(*) -- DOUBLE PRECISION array                 Workspace
     Note: the dimension of the array WK2 must be at least
     max(1,N).

 8:  IFAIL -- INTEGER                              Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     The matrix A is not positive-definite, possibly due to
     rounding errors.

IFAIL= 2
     Iterative refinement fails to improve the solution, i.e.,
     the matrix A is too ill-conditioned.
```

```
IFAIL= 3
     On entry N < 0,

     or        IA < max(1,N).

7. Accuracy

The computed solutions should be correct to full machine
accuracy. For a detailed error analysis see Wilkinson and Reinsch
[1] page 39.

8. Further Comments

                                                               3
The time taken by the routine is approximately proportional to n

The routine must not be called with the same name for parameters
B and C.

9. Example

To solve the set of linear equations Ax=b where

                           (5  7  6  5)
                           (7 10  8  7)
                         A=(6  8 10  9)
                           (5  7  9 10)

and

                               (23)
                               (32)
                             b=(33).
                               (31)

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

                  F04ATF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F04ATF calculates the accurate solution of a set of real linear
          equations with a single right-hand side, using an LU
          factorization with partial pivoting, and iterative refinement.

          2. Specification

                 SUBROUTINE F04ATF (A, IA, B, N, C, AA, IAA, WKS1, WKS2,
                1                   IFAIL)
                 INTEGER          IA, N, IAA, IFAIL
                 DOUBLE PRECISION A(IA,*), B(*), C(*), AA(IAA,*), WKS1(*),
                1                 WKS2(*)

          3. Description

          Given a set of real linear equations, Ax=b, the routine first
          computes an LU factorization of A with partial pivoting, PA=LU,
          where P is a permutation matrix, L is lower triangular and U is
          unit upper triangular. An approximation to x is found by forward
          and backward substitution in Ly=Pb and Ux=y. The residual vector
          r=b-Ax is then calculated using additional precision, and a
          correction d to x is found by solving LUd=r. x is replaced by x+d
          , and this iterative refinement of the solution is repeated until
          full machine accuracy is obtained.

 1:  A(IA,*) -- DOUBLE PRECISION array                      Input
     Note: the second dimension of the array A must be at least
     max(1,N).
     On entry: the n by n matrix A.

 2:  IA -- INTEGER                                          Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which F04ATF is called.
     Constraint: IA >= max(1,N).

 3:  B(*) -- DOUBLE PRECISION array                         Input
     Note: the dimension of the array B must be at least
     max(1,N).
     On entry: the right-hand side vector b.

 4:  N -- INTEGER                                           Input
     On entry: n, the order of the matrix A. Constraint: N >= 0.

 5:  C(*) -- DOUBLE PRECISION array                        Output
     Note: the dimension of the array C must be at least
     max(1,N).
     On exit: the solution vector x.

 6:  AA(IAA,*) -- DOUBLE PRECISION array                   Output
     Note: the second dimension of the array AA must be at least
     max(1,N).
     On exit: the triangular factors L and U, except that the
     unit diagonal elements of U are not stored.

 7:  IAA -- INTEGER                                         Input
     On entry:
     the first dimension of the array AA as declared in the
     (sub)program from which F04ATF is called.
     Constraint: IAA >= max(1,N).

 8:  WKS1(*) -- DOUBLE PRECISION array                  Workspace
     Note: the dimension of the array WKS1 must be at least
     max(1,N).

 9:  WKS2(*) -- DOUBLE PRECISION array                  Workspace
     Note: the dimension of the array WKS2 must be at least
     max(1,N).
```

```
10:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     The matrix A is singular, possibly due to rounding errors.

IFAIL= 2

     Iterative refinement fails to improve the solution, i.e.,
     the matrix A is too ill-conditioned.

IFAIL= 3
     On entry N < 0,

     or       IA < max(1,N),

     or       IAA < max(1,N).

7. Accuracy

The computed solutions should be correct to full machine
accuracy. For a detailed error analysis see Wilkinson and Reinsch
[1] page 107.

8. Further Comments

                                                                3
The time taken by the routine is approximately proportional to n

The routine must not be called with the same name for parameters
B and C.

9. Example

To solve the set of linear equations Ax=b where

                          ( 33  16  72)
                        A=(-24 -10 -57)
```

```
                                  ( -8  -4 -17)

          and

                                     (-359)
                                   b=( 281).
                                     (  85)

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

16.5.34 Solution of a set of real sparse linear equations

— nagf.ht —

```
\begin{page}{manpageXXf04axf}{NAG Documentation: f04axf}
\beginscroll
\begin{verbatim}

     F04AXF(3NAG)      Foundation Library (12/10/92)      F04AXF(3NAG)

          F04 -- Simultaneous Linear Equations                     F04AXF
                  F04AXF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F04AXF calculates the approximate solution of a set of real
          sparse linear equations with a single right-hand side, Ax=b or
           T
          A x=b, where A has been factorized by F01BRF or F01BSF.
```

2. Specification

```
       SUBROUTINE F04AXF (N, A, LICN, ICN, IKEEP, RHS, W, MTYPE,
      1                   IDISP, RESID)
       INTEGER          N, LICN, ICN(LICN), IKEEP(5*N), MTYPE,
      1                 IDISP(2)
       DOUBLE PRECISION A(LICN), RHS(N), W(N), RESID
```

3. Description

To solve a system of real linear equations Ax=b or A^T x=b, where A is a general sparse matrix, A must first be factorized by F01BRF or F01BSF. F04AXF then computes x by block forward or backward substitution using simple forward and backward substitution within each diagonal block.

The method is fully described in Duff [1].

4. References

[1] Duff I S (1977) MA28 -- a set of Fortran subroutines for sparse unsymmetric linear equations. A.E.R.E. Report R.8730. HMSO.

5. Parameters

```
 1:  N -- INTEGER                                            Input
     On entry: n, the order of the matrix A.

 2:  A(LICN) -- DOUBLE PRECISION array                       Input
     On entry: the non-zero elements in the factorization of the
     matrix A, as returned by F01BRF or F01BSF.

 3:  LICN -- INTEGER                                         Input
     On entry:
     the dimension of the arrays A and ICN as declared in the
     (sub)program from which F04AXF is called.

 4:  ICN(LICN) -- INTEGER array                              Input
     On entry: the column indices of the non-zero elements of
     the factorization, as returned by F01BRF or F01BSF.

 5:  IKEEP(5*N) -- INTEGER array                             Input
     On entry: the indexing information about the factorization,
     as returned by F01BRF or F01BSF.

 6:  RHS(N) -- DOUBLE PRECISION array                 Input/Output
     On entry: the right-hand side vector b. On exit: RHS is
     overwritten by the solution vector x.

 7:  W(N) -- DOUBLE PRECISION array                     Workspace

 8:  MTYPE -- INTEGER                                       Input
     On entry: MTYPE specifies the task to be performed:
          if MTYPE = 1, solve Ax=b,

                                T
          if MTYPE /= 1, solve A x=b.

 9:  IDISP(2) -- INTEGER array                              Input
     On entry: the values returned in IDISP by F01BRF.

10:  RESID -- DOUBLE PRECISION                             Output
     On exit: the value of the maximum residual,
              --
     max(|b - > a  x |), over all the unsatisfied equations, in
           i  -- ij j
              j
     case F01BRF or F01BSF has been used to factorize a singular
     or rectangular matrix.
```

6. Error Indicators and Warnings

None.

7. Accuracy

The accuracy of the computed solution depends on the conditioning of the original matrix. Since F04AXF is always used with either F01BRF or F01BSF, the user is recommended to set GROW = .TRUE. on entry to these routines and to examine the value of W(1) on exit (see the routine documents for F01BRF and F01BSF). For a detailed error analysis see Duff [1] page 17.

If storage for the original matrix is available then the error can be estimated by calculating the residual

$$r=b-Ax \quad (\text{or } b-A^T x)$$

and calling F04AXF again to find a correction (delta) for x by solving

$$A(\delta)=r \quad (\text{or } A^T(\delta)=r).$$

8. Further Comments

```
          If the factorized form contains (tau) non-zeros (IDISP(2) = (tau)
          ) then the time taken is very approximately 2(tau) times longer
          than the inner loop of full matrix code. Some advantage is taken
                                                         T
          of zeros in the right-hand side when solving A x=b (MTYPE /= 1).

          9. Example

          To solve the set of linear equations Ax=b where

                                  ( 5  0  0  0 0  0)
                                  ( 0  2 -1  2 0  0)
                                  ( 0  0  3  0 0  0)
                                A=(-2  0  0  1 1  0)
                                  (-1  0  0 -1 2 -3)
                                  (-1 -1  0  0 0  6)

          and

                                         (15)
                                         (12)
                                         (18)
                                       b=( 3).
                                         (-6)
                                         ( 0)

          The non-zero elements of A and indexing information are read in
          by the program, as described in the document for F01BRF.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

16.5.35 Real symmetric positive-definite tridiagonal linear equations

— nagf.ht —

```
\begin{page}{manpageXXf04faf}{NAG Documentation: f04faf}
```

```
\beginscroll
\begin{verbatim}

     F04FAF(3NAG)      Foundation Library (12/10/92)      F04FAF(3NAG)

          F04 -- Simultaneous Linear Equations                       F04FAF
                  F04FAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F04FAF calculates the approximate solution of a set of real
          symmetric positive-definite tridiagonal linear equations.

          2. Specification

                 SUBROUTINE F04FAF (JOB, N, D, E, B, IFAIL)
                 INTEGER          JOB, N, IFAIL
                 DOUBLE PRECISION D(N), E(N), B(N)

          3. Description

          F04FAF is based upon the Linpack routine DPTSL (see Dongarra et
          al [1]) and solves the equations

                                       Tx=b,

          where T is a real n by n symmetric positive-definite tridiagonal
          matrix, using a modified symmetric Gaussian elimination algorithm
                                  T
          to factorize T as T=MKM , where K is diagonal and M is a matrix
          of multipliers as described in Section 8.

          When the input parameter JOB is supplied as 1, then the routine
          assumes that a previous call to F04FAF has already factorized T;
          otherwise JOB must be supplied as 0.

          4. References

          [1]   Dongarra J J, Moler C B, Bunch J R and Stewart G W (1979)
                LINPACK Users' Guide. SIAM, Philadelphia.
```

```
5. Parameters

 1:  JOB -- INTEGER                                      Input
     On entry: specifies the job to be performed by F04FAF as
     follows:
     JOB = 0
           The matrix T is factorized and the equations Tx=b are
           solved for x.

     JOB = 1
           The matrix T is assumed to have already been
           factorized by a previous call to F04FAF with JOB = 0;
           the equations Tx=b are solved for x.

 2:  N -- INTEGER                                        Input
     On entry: n, the order of the matrix T. Constraint: N >= 1.

 3:  D(N) -- DOUBLE PRECISION array               Input/Output
     On entry: if JOB = 0, D must contain the diagonal elements
     of T. If JOB = 1, D must contain the diagonal matrix K, as
     returned by a previous call of F04FAF with JOB = 0. On
     exit: if JOB = 0, D is overwritten by the diagonal matrix K
     of the factorization. If JOB = 1, D is unchanged.

 4:  E(N) -- DOUBLE PRECISION array               Input/Output
     On entry: if JOB = 0, E must contain the super-diagonal
     elements of T, stored in E(2) to E(n). If JOB = 1, E must
     contain the off-diagonal elements of the matrix M, as
     returned by a previous call of F04FAF with JOB = 0. E(1) is
     not used. On exit: if JOB = 0, E(2) to E(n) are overwritten
     by the off-diagonal elements of the matrix M of the
     factorization. If JOB = 1, E is unchanged.

 5:  B(N) -- DOUBLE PRECISION array               Input/Output
     On entry: the right-hand side vector b. On exit: B is
     overwritten by the solution vector x.

 6:  IFAIL -- INTEGER                             Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
```

```
     On entry N < 1,

     or       JOB /= 0 or 1.

IFAIL= 2
     The matrix T is either not positive-definite or is nearly
     singular. This failure can only occur when JOB = 0 and
     inspection of the elements of D will give an indication of
     why failure has occurred. If an element of D is close to
     zero, then T is probably nearly singular; if an element of D
     is negative but not close to zero, then T is not positive-
     definite.

IFAILOverflow
     If overflow occurs during the execution of this routine,
     then either T is very nearly singular or an element of the
     right-hand side vector b is very large. In this latter case
     the equations should be scaled so that no element of b is
     very large. Note that to preserve symmetry it is necessary
                                                    T
     to scale by a transformation of the form (PTP )b=Px, where P
     is a diagonal matrix.

IFAILUnderflow
     Any underflows that occur during the execution of this
     routine are harmless.

7. Accuracy

The computed factorization (see Section 8) will satisfy the
equation

                               T
                            MKM =T+E

where ||E|| <=2(epsilon)||T|| , p=1,F,infty,
          p                  p

(epsilon) being the machine precision. The computed solution of

the equations Tx=b, say x, will satisfy an equation of the form

                            (T+F)x=b,

where F can be expected to satisfy a bound of the form

               ||F||<=(alpha)(epsilon)||T||,
(alpha) being a modest constant. This implies that the relative

error in x satisfies

                 ||x-x||
                 -------<=c(T)(alpha)(epsilon),
                  ||x||

where c(T) is the condition number of T with respect to

inversion. Thus if T is nearly singular, x can be expected to
have a large relative error.

8. Further Comments

The time taken by the routine is approximately proportional to n.

The routine eliminates the off-diagonal elements of T by
simultaneously performing symmetric Gaussian elimination from the
top and the bottom of T. The result is that T is factorized as

                                  T
                             T=MKM ,

where K is a diagonal matrix and M is a matrix of the form

                 (1  0  0 ..  0    0 0    .. 0 0    0 )
                 (m  1  0 ..  0    0 0    .. 0 0    0 )
                 ( 2                                  )
                 (0  m  1 ..  0    0 0    .. 0 0    0 )
                 (    3                               )
                 (.  .  . ..  .    . .    .. . .    . )
                 (.  .  . ..  .    . .    .. . .    . )
                 (0  0  0 ..  1    0 0    .. 0 0    0 )
               M=(0  0  0 ..  m    1 m    .. 0 0    0 )
                 (             j+1    j+2             )
                 (0  0  0 ..  0    0 ..   1 0  0    0 )
                 (.  .  . ..  .    . .    .. . .    . )
                 (.  .  . ..  .    . .    .. . .    . )
                 (0  0  0 ..  0    0 0    .. 1 m    0 )
                 (                               n-1  )
                 (0  0  0 ..  0    0 0    .. 0 1    m )
                 (                                   n)
                 (0  0  0 ..  0    0 0 .   . 0 0    1 )
```

```
          j being the integer part of n/2. (For example when n=5,j=2.) The
          diagonal elements of K are returned in D with k  in the ith
                                                         i
          element of D and m  is returned in the ith element of E.
                            i

          The routine fails with IFAIL = 2 if any diagonal element of K is
          non-positive. It should be noted that T may be nearly singular
          even if all the diagonal elements of K are positive, but in this
          case at least one element of K is almost certain to be small
          relative to |||T|||. If there is any doubt as to whether or not T
          is nearly singular, then the user should consider examining the
          diagonal elements of K.

          9. Example

          To solve the symmetric positive-definite equations

                                       Tx =b
                                         1  1

          and

                                       Tx =b
                                         2  2

          where

                         ( 4 -2  0  0 0)       ( 6)      (10)
                         (-2 10 -6  0 0)       ( 9)      ( 4)
                       T=( 0 -6 29 15 0),   b =( 2),  b =( 9).
                         ( 0  0 15 25 8)     1 (14)    2 (65)
                         ( 0  0  0  8 5)       ( 7)      (23)

          The equations are solved by two calls to F04FAF, the first with
          JOB = 0 and the second, using the factorization from the first
          call, with JOB = 1.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

16.5.36 Solution of a linear least-squares problem, $Ax = b$

— nagf.ht —

```
\begin{page}{manpageXXf04jgf}{NAG Documentation: f04jgf}
\beginscroll
\begin{verbatim}

     F04JGF(3NAG)      Foundation Library (12/10/92)      F04JGF(3NAG)

          F04 -- Simultaneous Linear Equations                       F04JGF
                  F04JGF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F04JGF finds the solution of a linear least-squares problem, Ax=b
          , where A is a real m by n (m>=n) matrix and b is an m element
          vector. If the matrix of observations is not of full rank, then
          the minimal least-squares solution is returned.

          2. Specification

                 SUBROUTINE F04JGF (M, N, A, NRA, B, TOL, SVD, SIGMA,
                1                   IRANK, WORK, LWORK, IFAIL)
                 INTEGER          M, N, NRA, IRANK, LWORK, IFAIL
                 DOUBLE PRECISION A(NRA,N), B(M), TOL, SIGMA, WORK(LWORK)
                 LOGICAL          SVD

          3. Description

          The minimal least-squares solution of the problem Ax=b is the
          vector x of minimum (Euclidean) length which minimizes the length
          of the residual vector r=b-Ax.

          The real m by n (m>=n) matrix A is factorized as

                                               (U)
                                            A=Q(0)

          where Q is an m by m orthogonal matrix and U is an n by n upper
```

triangular matrix. If U is of full rank, then the least-squares solution is given by

$$x=(U^{-1}\ 0)Q^T b.$$

If U is not of full rank, then the singular value decomposition of U is obtained so that U is factorized as

$$U=RDP^T,$$

where R and P are n by n orthogonal matrices and D is the n by n diagonal matrix

$$D=diag(\sigma_1,\sigma_2,...,\sigma_n),$$

with $\sigma_1 >= \sigma_2 >= ... \sigma_n >= 0$, these being the singular values of A. If the singular values $\sigma_{k+1},...,\sigma_n$ are negligible, but σ_k is not negligible, relative to the data errors in A, then the rank of A is taken to be k and the minimal least-squares solution is given by

$$x=P\begin{pmatrix} S^{-1} & 0 \\ 0 & 0 \end{pmatrix}\begin{pmatrix} R^T & 0 \\ 0 & I \end{pmatrix}Q^T b,$$

where $S=diag(\sigma_1,\sigma_2,...,\sigma_k)$.

This routine obtains the factorizations by a call to F02WDF(*).

The routine also returns the value of the standard error

$$\sigma = \sqrt{\frac{r^T r}{m-k}}, \quad \text{if } m>k,$$

$$= 0, \quad \text{if } m=k,\ r^T r \text{ being the residual sum of squares and } k \text{ the rank of A.}$$

4. References

[1] Lawson C L and Hanson R J (1974) Solving Least-squares Problems. Prentice-Hall.

5. Parameters

1: M -- INTEGER Input
On entry: m, the number of rows of A. Constraint: M >= N.

2: N -- INTEGER Input
On entry: n, the number of columns of A. Constraint: 1 <= N <= M.

3: A(NRA,N) -- DOUBLE PRECISION array Input/Output
On entry: the m by n matrix A. On exit: if SVD is returned as .FALSE., A} is overwritten by details of the QU factorization of A (see F02WDF(*) for further details). If SVD is returned as .TRUE., the first n rows of A are overwritten by the right-hand singular vectors, stored by rows; and the remaining rows of the array are used as workspace.

4: NRA -- INTEGER Input
On entry:
the first dimension of the array A as declared in the (sub)program from which F04JGF is called.
Constraint: NRA >= M.

5: B(M) -- DOUBLE PRECISION array Input/Output
On entry: the right-hand side vector b. On exit: the first n elements of B contain the minimal least-squares solution vector x. The remaining m-n elements are used for workspace.

6: TOL -- DOUBLE PRECISION Input
On entry: a relative tolerance to be used to determine the rank of A. TOL should be chosen as approximately the largest relative error in the elements of A. For example, if the elements of A are correct to about 4 significant figures then TOL should be set to about $5*10^{-4}$. See Section 8 for a description of how TOL is used to determine rank. If TOL is outside the range ((epsilon),1.0), where (epsilon) is the machine precision, then the value (epsilon) is used in place of TOL. For most problems this is unreasonably small.

7: SVD -- LOGICAL Output
On exit: SVD is returned as .FALSE. if the least-squares solution has been obtained from the QU factorization of A. In this case A is of full rank. SVD is returned as .TRUE. if the least-squares solution has been obtained from the singular value decomposition of A.

8: SIGMA -- DOUBLE PRECISION Output

On exit: the standard error, i.e., the value $\sqrt{r^T r/(m-k)}$ when m>k, and the value zero when m=k. Here r is the residual vector b-Ax and k is the rank of A.

9: IRANK -- INTEGER Output

On exit: k, the rank of the matrix A. It should be noted that it is possible for IRANK to be returned as n and SVD to be returned as .TRUE.. This means that the matrix U only just failed the test for non-singularity.

10: WORK(LWORK) -- DOUBLE PRECISION array Output

On exit: if SVD is returned as .FALSE., then the first n elements of WORK contain information on the QU factorization of A (see parameter A above and F02WDF(*)), and WORK(n+1) contains the condition number $||U||_E \, ||U^{-1}||_E$ of the upper triangular matrix U.

If SVD is returned as .TRUE., then the first n elements of WORK contain the singular values of A arranged in descending order and WORK(n+1) contains the total number of iterations taken by the QR algorithm. The rest of WORK is used as workspace.

11: LWORK -- INTEGER Input

On entry:
the dimension of the array WORK as declared in the (sub)program from which F04JGF is called.
Constraint: LWORK >= 4*N.

12: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

On entry N < 1,

or M < N,

or NRA < M,

or LWORK < 4*N.

IFAIL= 2
The QR algorithm has failed to converge to the singular values in 50*N iterations. This failure can only happen when the singular value decomposition is employed, but even then it is not likely to occur.

7. Accuracy

The computed factors Q, U, R, D and P^T satisfy the relations

$$Q\begin{pmatrix}U\\0\end{pmatrix}=A+E , Q\begin{pmatrix}R & 0\\0 & I\end{pmatrix}\begin{pmatrix}D\\0\end{pmatrix}P^T=A+F,$$

where

$$||E||_2 <=c_1 (epsilon)||A||_2 ,$$

$$||F||_2 <=c_2 (epsilon)||A||_2 ,$$

(epsilon) being the machine precision, and c_1 and c_2 being modest functions of m and n. Note that $||A||_2 =(sigma)_1$.

For a fuller discussion, covering the accuracy of the solution x see Lawson and Hanson [1], especially pp 50 and 95.

8. Further Comments

If the least-squares solution is obtained from the QU factorization then the time taken by the routine is approximately proportional to $n^2(3m-n)$. If the least-squares solution is obtained from the singular value decomposition then the time taken is approximately proportional to $n^2(3m+19n)$. The approximate proportionality factor is the same in each case.

This routine is column biased and so is suitable for use in paged

```
          environments.

          Following the QU factorization of A the condition number

                                            -1
                              c(U)=||U|| ||U  ||
                                        E       E

          is determined and if c(U) is such that

                                   c(U)*TOL>1.0

          then U is regarded as singular and the singular values of A are
          computed. If this test is not satisfied, U is regarded as non-
          singular and the rank of A is set to n. When the singular values
          are computed the rank of A, say k, is returned as the largest
          integer such that

                              (sigma) >TOL*(sigma) ,
                                     k            1

          unless (sigma) =0 in which case k is returned as zero. That is,
                        1
          singular values which satisfy (sigma) <=TOL*(sigma)  are regarded
                                               i             1
          as negligible because relative perturbations of order TOL can
          make such singular values zero.

          9. Example

          To obtain a least-squares solution for r=b-Ax, where

                            (0.05  0.05 0.25 -0.25)      (1)
                            (0.25  0.25 0.05 -0.05)      (2)
                            (0.35  0.35 1.75 -1.75)      (3)
                          A=(1.75  1.75 0.35 -0.35),   B=(4)
                            (0.30 -0.30 0.30  0.30)      (5)
                            (0.40 -0.40 0.40  0.40)      (6)

                                                   -4
          and the value TOL is to be taken as 5*10   .

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

16.5.37 Sparse symmetric positive-definite system linear equations

— nagf.ht —

```
\begin{page}{manpageXXf04maf}{NAG Documentation: f04maf}
\beginscroll
\begin{verbatim}

     F04MAF(3NAG)      Foundation Library (12/10/92)      F04MAF(3NAG)

          F04 -- Simultaneous Linear Equations                       F04MAF
                  F04MAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          To solve a sparse symmetric positive-definite system of linear
          equations, Ax=b, using a pre-conditioned conjugate gradient
          method, where A has been factorized by F01MAF.

          2. Specification

                 SUBROUTINE F04MAF (N, NZ, A, LICN, IRN, LIRN, ICN, B, ACC,
                1                   NOITS, WKEEP, WORK, IKEEP, INFORM,
                2                   IFAIL)
                 INTEGER          N, NZ, LICN, IRN(LIRN), LIRN, ICN(LICN),
                1                 NOITS(2), IKEEP(2*N), INFORM(4), IFAIL
                 DOUBLE PRECISION A(LICN), B(N), ACC(2), WKEEP(3*N), WORK
                1                 (3*N)

          3. Description

          F04MAF solves the n linear equations

                                     Ax=b,                               (1)

          where A is a sparse symmetric positive-definite matrix, following
          the incomplete Cholesky factorization by F01MAF, given by
```

$$C=PLDL^TP^T, \quad WAW=C+E,$$

where P is a permutation matrix, L is a unit lower triangular matrix, D is a diagonal matrix with positive diagonal elements, E is an error matrix representing elements dropped during the factorization and diagonal elements that have been modified to ensure that C is positive-definite, and W is a diagonal matrix, chosen to make the diagonal elements of WAW unity.

Equation (1) is solved by applying a pre-conditioned conjugate gradient method to the equations

$$(WAW)(W^{-1}x)=Wb, \qquad (2)$$

using C as the pre-conditioning matrix. Details of the conjugate gradient method are given in Munksgaard [1].

The iterative procedure is terminated if

$$||Wr||_2 <=(eta), \qquad (3)$$

where r is the residual vector r=b-Ax, $||r||_2$ denotes the Euclidean length of r, (eta) is a user-supplied tolerance and x is the current approximation to the solution. Notice that

$$Wr=Wb-(WAW)(W^{-1}x)$$

so that Wr is the residual of the normalised equations (2).

F04MAF is based on the Harwell Library routine MA31B.

4. References

[1] Munksgaard N (1980) Solving Sparse Symmetric Sets of Linear Equations by Pre-conditioned Conjugate Gradients. ACM Trans. Math. Softw. 6 206--219.

5. Parameters

1: N -- INTEGER Input
On entry: n, the order of the matrix A. Constraint: N >= 1.

2: NZ -- INTEGER Input
On entry: the number of non-zero elements in the upper

```
     triangular part of the matrix A, including the number of
     elements on the leading diagonal. Constraint: NZ >= N.

 3:  A(LICN) -- DOUBLE PRECISION array                   Input
     On entry: the first LROW elements, where LROW is the value
     supplied in INFORM(1), must contain details of the
     factorization, as returned by F01MAF.

 4:  LICN -- INTEGER                                     Input
     On entry: the length of the array A, as declared in the
     (sub)program from which F04MAF is called. It need never be
     larger than the value of LICN supplied to F01MAF.
     Constraint: LICN >= INFORM(1).

 5:  IRN(LIRN) -- INTEGER array                          Input
     On entry: the first LCOL elements, where LCOL is the value
     supplied in INFORM(2), must contain details of the
     factorization, as returned by F01MAF.

 6:  LIRN -- INTEGER                                     Input
     On entry: the length of the array IRN, as declared in the
     (sub)program from which F04MAF is called. It need never be
     larger than the value of LIRN supplied to F01MAF.
     Constraint: LIRN >= INFORM(2).

 7:  ICN(LICN) -- INTEGER array                          Input
     On entry: the first LROW elements, where LROW is the value
     supplied in INFORM(1), must contain details of the
     factorization, as returned by F01MAF.

 8:  B(N) -- DOUBLE PRECISION array               Input/Output
     On entry: the right-hand side vector b. On exit: B is
     overwritten by the solution vector x.

 9:  ACC(2) -- DOUBLE PRECISION array             Input/Output
     On entry: ACC(1) specifies the tolerance for convergence,
     (eta), in equation (3) of Section 3. If ACC(1) is outside
     the range [(epsilon),1], where (epsilon) is the machine
     precision, then the value (epsilon) is used in place of ACC
     (1). ACC(2) need not be set. On exit: ACC(2) contains the
     actual value of ||Wr||  at the final point. ACC(1) is
                           2
     unchanged.

10:  NOITS(2) -- INTEGER array                    Input/Output
     On entry: NOITS(1) specifies the maximum permitted number of
     iterations. If NOITS(1) < 1, then the value 100 is used in
     its place. NOITS(2) need not be set. On exit: NOITS(2)
     contains the number of iterations taken to converge. NOITS
     (1) is unchanged.
```

```
11:  WKEEP(3*N) -- DOUBLE PRECISION array                   Input
     On entry: WKEEP must be unchanged from the previous call of
     F01MAF.

12:  WORK(3*N) -- DOUBLE PRECISION array                   Output
     On exit: WORK(1) contains a lower bound for the condition
     number of A. The rest of the array is used for workspace.

13:  IKEEP(2*N) -- INTEGER array                            Input
     On entry: IKEEP must be unchanged from the previous call of
     F01MAF.

14:  INFORM(4) -- INTEGER array                             Input
     On entry: INFORM must be unchanged from the previous call of
     F01MAF.

15:  IFAIL -- INTEGER                                Input/Output
     For this routine, the normal use of IFAIL is extended to
     control the printing of error and warning messages as well
     as specifying hard or soft failure (see the Essential
     Introduction).

     Before entry, IFAIL must be set to a value with the decimal
     expansion cba, where each of the decimal digits c, b and a
     must have a value of 0 or 1.
     a=0   specifies hard failure, otherwise soft failure;

     b=0   suppresses error messages, otherwise error messages
           will be printed (see Section 6);

     c=0   suppresses warning messages, otherwise warning
           messages will be printed (see Section 6).
     The recommended value for inexperienced users is 110 (i.e.,
     hard failure with all messages printed).

     Unless the routine detects an error (see Section 6), IFAIL
     contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

For each error, an explanatory error message is output on the
current error message unit (as defined by X04AAF), unless
suppressed by the value of IFAIL on entry.

IFAIL= 1
     On entry N < 1,
     or       NZ < N,

     or       LICN < INFORM(1),

     or       LIRN < INFORM(2).

IFAIL= 2
     Convergence has not taken place within the requested NOITS
     (1) number of iterations. ACC(2) gives the value ||Wr|| ,
                                                             2
     for the final point. Either too few iterations have been
     allowed, or the requested convergence criterion cannot be
     met.

IFAIL= 3
     The matrix A is singular, or nearly singular. Singularity
     has been detected during the conjugate gradient iterations,
     so that the computations are not complete.

IFAIL= 4
     The matrix A is singular, or nearly singular. The message
     output on the current error message channel will include an
     estimate of the condition number of A. In the case of soft
     failure an approximate solution is returned such that the
     value ||Wr||  is given by ACC(2) and the estimate (a lower
                 2
     bound) of the condition number is returned in WORK(1).

7. Accuracy

On successful return, or on return with IFAIL = 2 or IFAIL = 4
the computed solution will satisfy equation (3) of Section 3,
with (eta) = ACC(2).

8. Further Comments

The time taken by the routine will depend upon the sparsity of
the factorization and the number of iterations required. The
number of iterations will be affected by the nature of the
factorization supplied by F01MAF. The more incomplete the
factorization, the higher the number of iterations required by
F04MAF.

When the solution of several systems of equations, all with the
same matrix of coefficients, A, is required, then F01MAF need be
called only once to factorize A. This is illustrated in the
context of an eigenvalue problem in the example program for
F02FJF.

9. Example
```

The example program illustrates the use of F01MAF in conjunction
with F04MAF to solve the 16 linear equations Ax=b, where

```
                 (1 a     a                      )
                 (a 1 a     a                    )
                 (  a 1 a     a                  )
                 (    a 1 0     a                )
                 (a     0 1 a     a              )
                 (  a     a 1 a     a            )
                 (    a     a 1 a     a          )
                 (      a     a 1 0     a        )
               A=(        a     0 1 a     a      )
                 (          a     a 1 a     a    )
                 (            a     a 1 a     a  )
                 (              a     a 1 0     a)
                 (                a     0 1 a    )
                 (                  a     a 1 a  )
                 (                    a     a 1 a)
                 (                      a     a 1)

          1
where a=- -.
          4

          T (  1  1  1  1  1      1  1      1  1  1  1  1)
         b =(  -  -  -  -  - 0 0  -  - 0 0  -  -  -  -  -)
            (  2  4  4  2  4      4  4      4  2  4  4  2)
```

The n by n matrix A arises in the solution of Laplace's equation
in a unit-square, using a five-point formula with a 6 by 6
discretisation, with unity on the boundaries.

The drop tolerance, DROPTL, is taken as 0.1 and the density
factor, DENSW, is taken as 0.8. The value IFAIL = 111 is used so
that advisory and error messages will be printed, but soft
failure would occur if IFAIL were returned as non-zero.

A relative accuracy of about 0.0001 is requested in the solution
from F04MAF, with a maximum of 50 iterations.

The example program for F02FJF illustrates the use of routines
F01MAF and F04MAF in solving an eigenvalue problem.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

     F04MBF(3NAG)      Foundation Library (12/10/92)      F04MBF(3NAG)

          F04 -- Simultaneous Linear Equations                      F04MBF
                  F04MBF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F04MBF solves a system of real sparse symmetric linear equations
          using a Lanczos algorithm.

          2. Specification

                 SUBROUTINE F04MBF (N, B, X, APROD, MSOLVE, PRECON, SHIFT,
                1                   RTOL, ITNLIM, MSGLVL, ITN, ANORM,
                2                   ACOND, RNORM, XNORM, WORK, RWORK,
                3                   LRWORK, IWORK, LIWORK, INFORM, IFAIL)
                 INTEGER          N, ITNLIM, MSGLVL, ITN, LRWORK, IWORK
                1                 (LIWORK), LIWORK, INFORM, IFAIL
                 DOUBLE PRECISION B(N), X(N), SHIFT, RTOL, ANORM, ACOND,
                1                 RNORM, XNORM, WORK(N,5), RWORK(LRWORK)
                 LOGICAL          PRECON
                 EXTERNAL         APROD, MSOLVE

          3. Description

          F04MBF solves the system of linear equations
```

(A-(lambda)I)x=b (3.1)

where A is an n by n sparse symmetric matrix and (lambda) is a scalar, which is of course zero if the solution of the equations

Ax=b

is required. It should be noted that neither A nor (A-(lambda)I) need be positive-definite.

(lambda) is supplied as the parameter SHIFT, and allows F04MBF to be used for finding eigenvectors of A in methods such as Rayleigh quotient iteration (see for example Lewis [1]), in which case (lambda) will be an approximation to an eigenvalue of A and b an approximation to an eigenvector of A.

The routine also provides an option to allow pre-conditioning and this will often reduce the number of iterations required by F04MBF.

F04MBF is based upon algorithm SYMMLQ (see Paige and Saunders [2]) and solves the equations by an algorithm based upon the

Lanczos process. Details of the method are given in Paige and Saunders [2]. The routine does not require A explicitly, but A is specified via a user-supplied routine APROD which, given an n element vector c, must return the vector z given by

z=Ac.

The pre-conditioning option is based on the following reasoning. If A can be expressed in the form

A=I+B

where B is of rank (rho), then the Lanczos process converges (in exact arithmetic) in at most (rho) iterations. If more generally A can be expressed in the form

A=M+C

where M is symmetric positive-definite and C has rank (rho), then

$$M^{-(1/2)}AM^{-(1/2)}=I+M^{-(1/2)}CM^{-(1/2)}$$

and $M^{-(1/2)}AM^{-(1/2)}$ also has rank (rho), and the Lanczos process
-(1/2) -(1/2)

applied to M AM would again converge in at most (rho) iterations. On a computer, the number of iterations may be greater than (rho), but the Lanczos process may still be expected to converge rapidly. F04MBF does not require $M^{-(1/2)}AM^{-(1/2)}$ to be formed explicitly, but implicitly solves the equations

$$M^{-(1/2)}(A-(\lambda)I)M^{-(1/2)}y=M^{-(1/2)}b\ ,\ y=M^{1/2}x \qquad (3.2)$$

with the user being required to supply a routine MSOLVE to solve the equations

$$Mz=c. \qquad (3.3)$$

For the pre-conditioning option to be effective, it is desirable that equations (3.3) can be solved efficiently. The example program in Section 9 illustrates the use of this option.

If we let r denote the residual vector

$$r=b-(A-(\lambda)I)x$$

corresponding to an iterate x, then, when pre-conditioning has not been requested, the iterative procedure is terminated if it is estimated that

$$||r||<=tol.||A-(\lambda)I||.||x||, \qquad (3.4)$$

where tol is a user-supplied tolerance, ||r|| denotes the Euclidean length of the vector r and ||A|| denotes the Frobenius (Euclidean) norm of the matrix A. When pre-conditioning has been requested, the iterative procedure is terminated if it is estimated that

$$||M^{-(1/2)}r||<=tol.||M^{-(1/2)}(A-(\lambda)I)M^{-(1/2)}||.||M^{1/2}x||. \qquad (3.5)$$

Note that

$$M^{-(1/2)}r=(M^{-(1/2)}b)-M^{-(1/2)}(A-(\lambda)I)M^{-(1/2)}(M^{1/2}x)$$

so that $M^{-(1/2)}r$ is the residual vector corresponding to equation (3.2). The routine will also terminate if it is estimated that

$$||A-(\lambda)I||.||x||>=||b||/(\epsilon), \qquad (3.6)$$

where (epsilon) is the machine precision, when pre-conditioning has not been requested; or if it is estimated that

```
   -(1/2)              -(1/2)      1/2       -(1/2)
||M      (A-(lambda)I)M      ||.||M   x||>=||M      b||/(epsilon)

                                                            (3.7)
```

when pre-conditioning has been requested. If (3.6) is satisfied then x is almost certainly an eigenvector of A corresponding to the eigenvalue (lambda). If (lambda) was set to 0 (for the solution of Ax=b), then this condition simply means that A is effectively singular.

5. Parameters

1: N -- INTEGER Input
On entry: n, the order of the matrix A. Constraint: N >= 1.

2: B(N) -- DOUBLE PRECISION array Input
On entry: the right-hand side vector b.

3: X(N) -- DOUBLE PRECISION array Output
On exit: the solution vector x.

4: APROD -- SUBROUTINE, supplied by the user.
External Procedure
APROD must return the vector y=Ax for a given vector x.

Its specification is:

```
       SUBROUTINE APROD (IFLAG, N, X, Y, RWORK, LRWORK,
      1                  IWORK,LIWORK)
       INTEGER          IFLAG, N, LRWORK, LIWORK, IWORK
      1                 (LIWORK)
       DOUBLE PRECISION X(N), Y(N), RWORK(LRWORK)
```

1: IFLAG -- INTEGER Input/Output
On entry: IFLAG is always non-negative. On exit: IFLAG may be used as a flag to indicate a failure in the

```
             computation of  Ax.   If IFLAG is negative on exit from
             APROD, F04MBF will exit immediately with IFAIL set to
             IFLAG.

          2: N -- INTEGER                                      Input
             On entry: n, the order of the matrix A.

          3: X(N) -- DOUBLE PRECISION array                    Input
             On entry: the vector x for which Ax is required.

          4: Y(N) -- DOUBLE PRECISION array                   Output
             On exit: the vector y=Ax.

          5: RWORK(LRWORK) -- DOUBLE PRECISION array  User Workspace

          6: LRWORK -- INTEGER                                 Input

          7: IWORK(LIWORK) -- INTEGER array           User Workspace

          8: LIWORK -- INTEGER                                 Input
             APROD is called from F04MBF with the parameters RWORK,
             LRWORK, IWORK and LIWORK as supplied to F04MBF. The
             user is free to use the arrays RWORK and IWORK to
             supply information to APROD and MSOLVE as an
             alternative to using COMMON.
        APROD must be declared as EXTERNAL in the (sub)program
        from which F04MBF is called. Parameters denoted as
        Input must not be changed by this procedure.

    5:  MSOLVE -- SUBROUTINE, supplied by the user.
                                                  External Procedure
        MSOLVE is only referenced when PRECON is supplied as .TRUE..
        When PRECON is supplied as .FALSE., then F04MBF may be
        called with APROD as the actual argument for MSOLVE. When
        PRECON is supplied as .TRUE., then MSOLVE must return the
        solution y of the equations My=x for a given vector x, where
        M must be symmetric positive-definite.

        Its specification is:

               SUBROUTINE MSOLVE (IFLAG, N, X, Y, RWORK,
              1                   LRWORK, IWORK,LIWORK)
               INTEGER          IFLAG, N, LRWORK, LIWORK, IWORK
              1                 (LIWORK)
               DOUBLE PRECISION X(N), Y(N), RWORK(LRWORK)

          1: IFLAG -- INTEGER                           Input/Output
             On entry: IFLAG is always non-negative. On exit: IFLAG
             may be used as a flag to indicate a failure in the
             solution of My=x.
             If IFLAG is negative on exit from MSOLVE, F04MBF will
             exit immediately with IFAIL set to IFLAG.

         2:  N -- INTEGER                                      Input
             On entry: n, the order of the matrix M.

         3:  X(N) -- DOUBLE PRECISION array                    Input
             On entry: the vector x for which the equations My=x are
             to be solved.

         4:  Y(N) -- DOUBLE PRECISION array                   Output
             On exit: the solution to the equations My=x.

         5:  RWORK(LRWORK) -- DOUBLE PRECISION array  User Workspace

         6:  LRWORK -- INTEGER                                 Input

         7:  IWORK(LIWORK) -- INTEGER array           User Workspace

         8:  LIWORK -- INTEGER                                 Input
             MSOLVE is called from F04MBF with the parameters RWORK,
             LRWORK, IWORK and LIWORK as supplied to F04MBF. The
             user is free to use the arrays RWORK and IWORK to
             supply information to APROD and MSOLVE as an
             alternative to using COMMON.
        MSOLVE must be declared as EXTERNAL in the (sub)program
        from which F04MBF is called. Parameters denoted as
        Input must not be changed by this procedure.

    6:  PRECON -- LOGICAL                                     Input
        On entry: PRECON specifies whether or not pre-conditioning
        is required. If PRECON = .TRUE., then pre-conditioning will
        be invoked and MSOLVE will be referenced by F04MBF; if
        PRECON = .FALSE., then MSOLVE is not referenced.

    7:  SHIFT -- DOUBLE PRECISION                             Input
        On entry: the value of (lambda). If the equations Ax=b are
        to be solved, then SHIFT must be supplied as zero.

    8:  RTOL -- DOUBLE PRECISION                              Input
        On entry: the tolerance for convergence, tol, of equation
        (3.4). RTOL should not normally be less than (epsilon),
        where (epsilon) is the machine precision.

    9:  ITNLIM -- INTEGER                                     Input
        On entry: an upper limit on the number of iterations. If
        ITNLIM <= 0, then the value N is used in place of ITNLIM.

   10:  MSGLVL -- INTEGER                                     Input
```

```
     On entry: the level of printing from F04MBF. If MSGLVL <= 0,
     then no printing occurs, but otherwise messages will be
     output on the advisory message channel (see X04ABF). A
     description of the printed output is given in Section 5.1
     below. The level of printing is determined as follows:
     MSGLVL <= 0
           No printing.

     MSGLVL = 1
           A brief summary is printed just prior to return from
           F04MBF.

     MSGLVL >= 2
           A summary line is printed periodically to monitor the
           progress of F04MBF, together with a brief summary just
           prior to return from F04MBF.

 11: ITN -- INTEGER                                        Output
     On exit: the number of iterations performed.

 12: ANORM -- DOUBLE PRECISION                             Output
     On exit: an estimate of ||A-(lambda)I|| when PRECON =
                   -(1/2)              -(1/2)
     .FALSE., and ||M      (A-(lambda)I)M      || when PRECON =
     .TRUE..

 13: ACOND -- DOUBLE PRECISION                             Output
     On exit: an estimate of the condition number of (A-
     (lambda)I) when PRECON = .FALSE., and of
      -(1/2)              -(1/2)
     M      (A-(lambda)I)M       when PRECON = .TRUE.. This will
     usually be a substantial under-estimate.

 14: RNORM -- DOUBLE PRECISION                             Output
     On exit: ||r||, where r=b-(A-(lambda)I)x and x is the
     solution returned in X.

 15: XNORM -- DOUBLE PRECISION                             Output
     On exit: ||x||, where x is the solution returned in X.

 16: WORK(5*N) -- DOUBLE PRECISION array                Workspace

 17: RWORK(LRWORK) -- DOUBLE PRECISION array       User Workspace
     RWORK is not used by F04MBF, but is passed directly to
     routines APROD and MSOLVE and may be used to pass
     information to these routines.

 18: LRWORK -- INTEGER                                      Input
     On entry: the length of the array RWORK as declared in the
     (sub)program from which F04MBF is called. Constraint: LRWORK
     >= 1.

19:  IWORK(LIWORK) -- INTEGER array                User Workspace
     IWORK is not used by F04MBF, but is passed directly to
     routines APROD and MSOLVE and may be used to pass
     information to these routines.

20:  LIWORK -- INTEGER                                       Input
     On entry: the length of the array IWORK as declared in the
     (sub)program from which F04MBF is called. Constraint: LIWORK
     >= 1.

21:  INFORM -- INTEGER                                      Output
     On exit: the reason for termination of F04MBF as follows:
     INFORM = 0
           The right-hand side vector b=0 so that the exact
           solution is x=0. No iterations are performed in this
           case.

     INFORM = 1
           The termination criterion of equation (3.4) has been
           satisfied with tol as the value supplied in RTOL.

     INFORM = 2
           The termination criterion of equation (3.4) has been
           satisfied with tol equal to (epsilon), where (epsilon)
           is the machine precision. The value supplied in RTOL
           must have been less than (epsilon) and was too small
           for the machine.

     INFORM = 3
           The termination criterion of equation (3.5) has been
           satisfied so that X is almost certainly an eigenvector
           of A corresponding to the eigenvalue SHIFT.
     The values INFORM = 4 and INFORM = 5 correspond to failure
     with IFAIL = 3 or IFAIL = 2 respectively (see Section 6) and
     when IFAIL is negative, INFORM will be set to the same
     negative value.

22:  IFAIL -- INTEGER                                 Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

5.1. Description of the Printed Output

When MSGLVL > 0, then F04MBF will produce output (except in the
case where the routine fails with IFAIL = 1) on the advisory
message channel (see X04ABF ).

The following notation is used in the output.

   Output     Meaning

               -(1/2)
   RBAR       M      (b-(A-(lambda)I)x)=r

               -(1/2)              -(1/2)
   ABAR       M      (A-(lambda)I)M      =A

               1/2
   Y          M   x

   R          b-(A-(lambda)I)x

   NORM(A)    ||A||

Of course, when pre-conditioning has not been requested then the
first three reduce to (b-(A-(lambda)I)x), (A-(lambda)I) and x
respectively. When MSGLVL >= 2 then some initial information is
printed and the following notation is used.

   Output     Meaning

                T -1  1/2
   BETA1      (b M  b)   ==(beta)
                                 1

                        2  -(1/2)  T  -(1/2)  -(1/2)   -(1/2)
   ALFA1      (1/(beta) ) (M      b) (M      AM      )(M      b)
                      1
              ==(alpha)
                      1
and a summary line is printed periodically giving the following
information:

   Output     Meaning

   ITN        Iteration number, k.

                                             L         L
   X1(LQ)     The first element of the vector x , where x  is the
                                             k         k
              current iterate. See Paige and Saunders [2] for
              details.

                                             C         C
```

X1(CG) The first element of the vector x_k, where x_k is the vector that would be obtained by conjugate gradients. See Paige and Saunders [2] for details.

NORM(RBAR) $||r||$, where r is as defined above and x is either x_k^L or x_k^C depending upon which is the best current approximation to the solution. (See LQ/CG below).

NORM(T) The value $||T_k||$, where T_k is the tridiagonal matrix of the Lanczos process. This increases monotonically and is a lower bound on $||A||$.

COND(L) A monotonically increasing lower bound on the condition number of A, $||A||||(A)^{-1}||$.

LQ/CG L is printed if x_k^L is the best current approximation to the solution and C is printed otherwise.

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL< 0
A negative value of IFAIL indicates an exit from F04MBF because the user has set IFLAG negative in APROD or MSOLVE. The value of IFAIL will be the same as the user's setting of IFLAG.

IFAIL= 1
On entry N < 1,

or LRWORK < 1,

or LIWORK < 1.

IFAIL= 2
The pre-conditioning matrix M does not appear to be positive-definite. The user should check that MSOLVE is

```
     working correctly.

IFAIL= 3
     The limit on the number of iterations has been reached. If
     IFAIL = 1 on entry then the latest approximation to the
     solution is returned in X and the values ANORM, ACOND, RNORM
     and XNORM are also returned.

The value of INFORM contains additional information about the
termination of the routine and users must examine INFORM to judge
whether the routine has performed successfully for the problem in
hand. In particular INFORM = 3 denotes that the matrix A-
(lambda)I is effectively singular: if the purpose of calling
F04MBF is to solve a system of equations Ax=b, then this
condition must be regarded as a failure, but if the purpose is to
compute an eigenvector, this result would be very satisfactory.

7. Accuracy

The computed solution x will satisfy the equation

                       r=b-(A-(lambda)I)x

where the value ||r|| is as returned in the parameter RNORM.

8. Further Comments

The time taken by the routine is likely to be principally
determined by the time taken in APROD and, when pre-conditioning
has been requested, in MSOLVE. Each of these routines is called
once every iteration.

The time taken by the remaining operations in F04MBF is
approximately proportional to n.

9. Example

To solve the 10 equations Ax=b given by

                  (2 1 0 0 0 0 0 0 0 3)      (6)
                  (1 2 1 0 0 0 0 0 0 0)      (4)
                  (0 1 2 1 0 0 0 0 0 0)      (4)
                  (0 0 1 2 1 0 0 0 0 0)      (4)
                  (0 0 0 1 2 1 0 0 0 0)      (4)
                A=(0 0 0 0 1 2 1 0 0 0),   b=(4).
                  (0 0 0 0 0 1 2 1 0 0)      (4)
                  (0 0 0 0 0 0 1 2 1 0)      (4)
                  (0 0 0 0 0 0 0 1 2 1)      (4)
                  (3 0 0 0 0 0 0 0 1 2)      (6)
```

```
          The tridiagonal part of A is positive-definite and such
          tridiagonal equations can be solved efficiently by F04FAF. The
          form of A suggests that this tridiagonal part is a good candidate
          for the pre-conditioning matrix M and so we illustrate the use of
          F04MBF by pre-conditioning with the 10 by 10 matrix

                                    (2 1 0 ... 0)
                                    (1 2 1 ... 0)
                                    (0 1 2 ... 0)
                                  M=(. . .   .  ).
                                    (. . .   .  )
                                    (. . .   .  )
                                    (0 0 0 ... 2)

          Since A-M has only 2 non-zero elements and is obviously of rank
          2, we can expect F04MBF to converge very quickly in this example.
          Of course, in practical problems we shall not usually be able to
          make such a good choice of M.

                                                     -5
          The example sets the tolerance RTOL = 10   .

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

F04 -- Simultaneous Linear Equations F04MCF

F04MCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F04MCF computes the approximate solution of a system of real linear equations with multiple right-hand sides, $AX=B$, where A is a symmetric positive-definite variable-bandwidth matrix, which has previously been factorized by F01MCF. Related systems may also be solved.

2. Specification

```
       SUBROUTINE F04MCF (N, AL, LAL, D, NROW, IR, B, NRB,
      1                   ISELCT, X, NRX, IFAIL)
       INTEGER          N, LAL, NROW(N), IR, NRB, ISELCT, NRX,
      1                 IFAIL
       DOUBLE PRECISION AL(LAL), D(N), B(NRB,IR), X(NRX,IR)
```

3. Description

The normal use of this routine is the solution of the systems $AX=B$, following a call of F01MCF to determine the Cholesky factorization $A=LDL^T$ of the symmetric positive-definite variable-bandwidth matrix A.

However, the routine may be used to solve any one of the following systems of linear algebraic equations:

(1) $LDL^TX = B$ (usual system),

(2) $LDX = B$ (lower triangular system),

(3) $DL^TX = B$ (upper triangular system),

(4) $LL^TX = B$

(5) $LX = B$ (unit lower triangular system),

(6) $L^TX = B$ (unit upper triangular system).

```
L denotes a unit lower triangular variable-bandwidth matrix of
order n, D a diagonal matrix of order n, and B a set of right-
hand sides.

The matrix L is represented by the elements lying within its
envelope i.e., between the first non-zero of each row and the
diagonal (see Section 9 for an example). The width NROW(i) of the
ith row is the number of elements between the first non-zero
element and the element on the diagonal inclusive.

4. References

      Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

 1:  N -- INTEGER                                          Input
     On entry: n, the order of the matrix L. Constraint: N >= 1.

 2:  AL(LAL) -- DOUBLE PRECISION array                     Input
     On entry: the elements within the envelope of the lower
     triangular matrix L, taken in row by row order, as returned
     by F01MCF. The unit diagonal elements of L must be stored
     explicitly.

 3:  LAL -- INTEGER                                        Input
     On entry:
     the dimension of the array AL as declared in the
     (sub)program from which F04MCF is called.
     Constraint: LAL >= NROW(1) + NROW(2) +... + NROW(n).

 4:  D(N) -- DOUBLE PRECISION array                        Input
     On entry: the diagonal elements of the diagonal matrix D. D
     is not referenced if ISELCT >= 4.

 5:  NROW(N) -- INTEGER array                              Input
     On entry: NROW(i) must contain the width of row i of L,
     i.e.,the number of elements between the first (leftmost)
     non-zero element and the element on the diagonal, inclusive.
     Constraint: 1 <= NROW(i)<=i.

 6:  IR -- INTEGER                                         Input
     On entry: r, the number of right-hand sides. Constraint: IR
     >= 1.

 7:  B(NRB,IR) -- DOUBLE PRECISION array                   Input
     On entry: the n by r right-hand side matrix B. See also
     Section 8.
```

8: NRB -- INTEGER Input
On entry:
the first dimension of the array B as declared in the
(sub)program from which F04MCF is called.
Constraint: NRB >= N.

9: ISELCT -- INTEGER Input
On entry: ISELCT must specify the type of system to be
solved, as follows:

ISELCT = 1: solve $LDL^T X = B$,

ISELCT = 2: solve $LDX = B$,

ISELCT = 3: solve $DL^T X = B$,

ISELCT = 4: solve $LL^T X = B$,

ISELCT = 5: solve $LX = B$,

ISELCT = 6: solve $L^T X = B$.

10: X(NRX,IR) -- DOUBLE PRECISION array Output
On exit: the n by r solution matrix X. See also Section 8.

11: NRX -- INTEGER Input
On entry:
the first dimension of the array X as declared in the
(sub)program from which F04MCF is called.
Constraint: NRX >= N.

12: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
On entry N < 1,

```
     or       for some i, NROW(i)<1 or NROW(i) > i,

     or       LAL < NROW(1) + NROW(2) +... + NROW(N).

IFAIL= 2

     On entry IR < 1,

     or       NRB < N,

     or       NRX < N.

IFAIL= 3
     On entry ISELCT < 1,

     or       ISELCT > 6.

IFAIL= 4
     The diagonal matrix D is singular, i.e., at least one of the
     elements of D is zero. This can only occur if ISELCT <= 3.

IFAIL= 5
     At least one of the diagonal elements of L is not equal to
     unity.

7. Accuracy

The usual backward error analysis of the solution of triangular
system applies: each computed solution vector is exact for
slightly perturbed matrices L and D, as appropriate (cf.
Wilkinson and Reinsch [1] pp 25--27, 54--55).

8. Further Comments

The time taken by the routine is approximately proportional to
pr, where

                 p=NROW(1)+NROW(2)+...+NROW(n).

Unless otherwise stated in the Users' Note for your
implementation, the routine may be called with the same actual
array supplied for the parameters B and X, in which case the
solution matrix will overwrite the right-hand side matrix.
However this is not standard Fortran 77 and may not work in all
implementations.

9. Example

To solve the system of equations AX=B, where
```

```
                             (1  2  0  0  5  0)
                             (2  5  3  0 14  0)
                             (0  3 13  0 18  0)
                           A=(0  0  0 16  8 24)
                             (5 14 18  8 55 17)
                             (0  0  0 24 17 77)

          and

                                  ( 6 -10)
                                  (15 -21)
                                  (11  -3)
                                B=( 0  24)
                                  (51 -39)
                                  (46  67)

          Here A is symmetric and positive-definite and must first be
          factorized by F01MCF.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

       INTEGER          M, N, ITNLIM, MSGLVL, ITN, LRWORK, IWORK
      1                 (LIWORK), LIWORK, INFORM, IFAIL
       DOUBLE PRECISION B(M), X(N), SE(N), DAMP, ATOL, BTOL,
      1                 CONLIM, ANORM, ACOND, RNORM, ARNORM,
      2                 XNORM, WORK(N,2), RWORK(LRWORK)
       EXTERNAL         APROD
```

3. Description

F04QAF can be used to solve a system of linear equations

$$Ax=b \qquad (3.1)$$

where A is an n by n sparse unsymmetric matrix, or can be used to solve linear least-squares problems, so that F04QAF minimizes the value (rho) given by

$$\rho=\|r\|, \quad r=b-Ax \qquad (3.2)$$

where A is an m by n sparse matrix and $\|r\|$ denotes the Euclidean length of r so that $\|r\|^2=r^Tr$. A damping parameter, (lambda), may be included in the least-squares problem in which case F04QAF minimizes the value (rho) given by

$$\rho^2=\|r\|^2+\lambda^2\|x\|^2 \qquad (3.3)$$

(lambda) is supplied as the parameter DAMP and should of course be zero if the solution to problems (3.1) or (3.2) is required. Minimizing (rho) in (3.3) is often called ridge regression.

F04QAF is based upon algorithm LSQR (see Paige and Saunders [1] and [2]) and solves the problems by an algorithm based upon the Lanczos process. Details of the method are given in [1]. The routine does not require A explicitly, but A is specified via a user-supplied routine APROD which must perform the operations ($y+Ax$) and ($x+A^T y$) for a given n element vector x and m element vector y. A parameter to APROD specifies which of the two operations is required on a given entry.

The routine also returns estimates of the standard errors of the sample regression coefficients (x_i, for i=1,2,...,n) given by the diagonal elements of the estimated variance-covariance matrix V. When problem (3.2) is being solved and A is of full rank, then V is given by

$$V=s^2(A^TA)^{-1},\quad s^2=\rho^2/(m-n),\quad m>n$$

and when problem (3.3) is being solved then V is given by

$$V=s^2(A^TA+\lambda^2 I)^{-1},\quad s^2=\rho^2/m,\quad \lambda\neq 0.$$

Let A denote the matrix

$$A=A,\quad \lambda=0\ ;\ A=\begin{pmatrix}A\\ \lambda I\end{pmatrix},\quad \lambda\neq 0, \qquad (3.4)$$

let r denote the residual vector

$$r=r,\quad \lambda=0\ ;\ r=\begin{pmatrix}b\\ 0\end{pmatrix}-Ax,\quad \lambda\neq 0 \qquad (3.5)$$

corresponding to an iterate x, so that $\rho=||r||$ is the function being minimized, and let $||A||$ denote the Frobenius (Euclidean) norm of A. Then the routine accepts x as a solution if it is estimated that one of the following two conditions is satisfied:

$$\rho\le tol\ ||A||.||x||+tol\ ||b|| \qquad (3.6)$$

$$||A^T r|| \le tol_1 ||A||(\rho) \qquad (3.7)$$

where tol_1 and tol_2 are user-supplied tolerances which estimate the relative errors in A and b respectively. Condition (3.6) is appropriate for compatible problems where, in theory, we expect the residual to be zero and will be satisfied by an acceptable solution x to a compatible problem. Condition (3.7) is appropriate for incompatible systems where we do not expect the residual to be zero and is based upon the observation that, in theory,

$$A^T r=0$$

when x is a solution to the least-squares problem, and so (3.7) will be satisfied by an acceptable solution x to a linear least-squares problem.

The routine also includes a test to prevent convergence to solutions, x, with unacceptably large elements. This can happen if A is nearly singular or is nearly rank deficient. If we let

the singular values of A be

$$(\sigma)_1 \ge (\sigma)_2 \ge \ldots \ge (\sigma)_n \ge 0$$

then the condition number of A is defined as

$$cond(A)=(\sigma)_1/(\sigma)_k$$

where $(\sigma)_k$ is the smallest non-zero singular value of A and

hence k is the rank of A. When k<n, then A is rank deficient, the least-squares solution is not unique and F04QAF will normally

converge to the minimal length solution. In practice A will not have exactly zero singular values, but may instead have small singular values that we wish to regard as zero.

The routine provides for this possibility by terminating if

$$\mathrm{cond}(A)>=c_{lim} \qquad (3.8)$$

where c_{lim} is a user-supplied limit on the condition number of A. For problem (3.1) termination with this condition indicates that A is nearly singular and for problem (3.2) indicates that A is nearly rank deficient and so has near linear dependencies in its columns. In this case inspection of $||r||$, $||A^T r||$ and $||x||$, which are all returned by the routine, will indicate whether or not an acceptable solution has been found. Condition (3.8), perhaps in conjunction with (lambda)/=0, can be used to try and ' regularise' least-squares solutions. A full discussion of the stopping criteria is given in Section 6 of reference Paige and Saunders [1].

Introduction of a non-zero damping parameter (lambda) tends to reduce the size of the computed solution and to make its components less sensitive to changes in the data, and F04QAF is applicable when a value of (lambda) is known a priori. To have an

effect, (lambda) should normally be at least \/(epsilon)||A|| where (epsilon) is the machine precision. For further discussion see Paige and Saunders [2] and the references given there.

Whenever possible the matrix A should be scaled so that the relative errors in the elements of A are all of comparable size. Such a scaling helps to prevent the least-squares problem from being unnecessarily sensitive to data errors and will normally reduce the number of iterations required. At the very least, in the absence of better information, the columns of A should be scaled to have roughly equal column length.

5. Parameters

1: M -- INTEGER Input
On entry: m, the number of rows of the matrix A.
Constraint: M >= 1.

2: N -- INTEGER Input
On entry: n, the number of columns of the matrix A.
Constraint: N >= 1.

3: B(M) -- DOUBLE PRECISION array Input/Output
On entry: the right-hand side vector b. On exit: the array is overwritten.

4: X(N) -- DOUBLE PRECISION array Output
On exit: the solution vector x.

5: SE(N) -- DOUBLE PRECISION array Output
On exit: the estimates of the standard errors of the components of x. Thus SE(i) contains an estimate of the element v_{ii} of the estimated variance-covariance matrix V.
The estimates returned in SE will be the lower bounds on the actual estimated standard errors, but will usually have at least one correct figure.

6: APROD -- SUBROUTINE, supplied by the user.
External Procedure
APROD must perform the operations y:=y+Ax and $x:=x+A^T y$ for given vectors x and y.

Its specification is:

```
       SUBROUTINE APROD (MODE, M, N, X, Y, RWORK,
      1                  LRWORK, IWORK, LIWORK)
       INTEGER          MODE, M, N, LRWORK, LIWORK,
      1                 IWORK(LIWORK)
       DOUBLE PRECISION X(N), Y(M), RWORK(LRWORK)
```

1: MODE -- INTEGER Input/Output
On entry: MODE specifies which operation is to be performed:

If MODE = 1, then APROD must compute y+Ax.

If MODE = 2, then APROD must compute $x+A^T y$.

On exit: MODE may be used as a flag to indicate a failure in the computation of y+Ax or $x+A^T y$. If MODE is negative on exit from APROD, F04QAF will exit immediately with IFAIL set to MODE.

2: M -- INTEGER Input
On entry: m, the number of rows of A.

3: N -- INTEGER Input
On entry: n, the number of columns of A.

4: X(N) -- DOUBLE PRECISION array Input/Output
On entry: the vector x. On exit: if MODE = 1, X must be unchanged;

If MODE = 2, X must contain $x+A^T y$.

5: Y(M) -- DOUBLE PRECISION array Input/Output
On entry: the vector y. On exit: if MODE = 1, Y must contain y+Ax;

If MODE = 2, Y must be unchanged.

6: RWORK(LRWORK) -- DOUBLE PRECISION array User Workspace

7: LRWORK -- INTEGER Input

8: IWORK(LIWORK) -- INTEGER array User Workspace

9: LIWORK -- INTEGER Input
APROD is called from F04QAF with the parameters RWORK, LRWORK, IWORK and LIWORK as supplied to F04QAF. The user is free to use the arrays RWORK and IWORK to supply information to APROD as an alternative to using COMMON.

APROD must be declared as EXTERNAL in the (sub)program from which F04QAF is called. Parameters denoted as Input must not be changed by this procedure.

7: DAMP -- DOUBLE PRECISION Input
On entry: the value (lambda). If either problem (3.1) or problem (3.2) is to be solved, then DAMP must be supplied as zero.

```
 8:  ATOL -- DOUBLE PRECISION                               Input
     On entry: the tolerance, tol , of the convergence criteria
                                 1
     (3.6) and (3.7); it should be an estimate of the largest
     relative error in the elements of A. For example, if the
     elements of A are correct to about 4 significant figures,
                                           -4
     then ATOL should be set to about 5*10  . If ATOL is supplied
     as less than (epsilon), where (epsilon) is the machine
     precision, then the value (epsilon) is used in place of
     ATOL.

 9:  BTOL -- DOUBLE PRECISION                               Input
     On entry: the tolerance, tol , of the convergence criterion
                                 2
     (3.6);  it should be an estimate of the largest relative
     error in the elements of B. For example, if the elements of
     B are correct to about 4 significant figures, then BTOL
                                 -4
     should be set to about 5*10  . If BTOL is supplied as less
     than (epsilon), where (epsilon) is the machine precision,
     then the value (epsilon) is used in place of BTOL.

10:  CONLIM -- DOUBLE PRECISION                             Input
     On entry: the value c    of equation  (3.8); it should be an
                          lim

     upper limit on the condition number of A. CONLIM should not
     normally be chosen much larger than 1.0/ATOL. If CONLIM is
     supplied as zero then the value 1.0/(epsilon), where
     (epsilon) is the machine precision, is used in place of
     CONLIM.

11:  ITNLIM -- INTEGER                                      Input
     On entry: an upper limit on the number of iterations. If
     ITNLIM <= 0, then the value N is used in place of ITNLIM,
     but for ill-conditioned problems a higher value of ITNLIM is
     likely to be necessary.

12:  MSGLVL -- INTEGER                                      Input
     On entry: the level of printing from F04QAF. If MSGLVL <= 0,
     then no printing occurs, but otherwise messages will be
     output on the advisory message channel (see X04ABF). A
     description of the printed output is given in Section 5.2
     below. The level of printing is determined as follows:
     MSGLVL <= 0
           No printing.

     MSGLVL = 1
```

```
             A brief summary is printed just prior to return from
             F04QAF.

       MSGLVL >= 2
             A summary line is printed periodically to monitor the
             progress of F04QAF, together with a brief summary just
             prior to return from F04QAF.

  13:  ITN -- INTEGER                                        Output
       On exit: the number of iterations performed.

  14:  ANORM -- DOUBLE PRECISION                             Output

       On exit: an estimate of ||A|| for the matrix A of equation
       (3.4).

  15:  ACOND -- DOUBLE PRECISION                             Output

       On exit: an estimate of cond(A) which is a lower bound.

  16:  RNORM -- DOUBLE PRECISION                             Output

       On exit: an estimate of ||r|| for the residual,  r, of
       equation (3.5) corresponding to the solution x returned in

       X. Note that ||r|| is the function being minimized.

  17:  ARNORM -- DOUBLE PRECISION                            Output
                                            T
       On exit: an estimate of the ||A r|| corresponding to the
       solution x returned in X.

  18:  XNORM -- DOUBLE PRECISION                             Output
       On exit: an estimate of ||x|| for the solution x returned in
       X.

  19:  WORK(2*N) -- DOUBLE PRECISION array                Workspace

  20:  RWORK(LRWORK) -- DOUBLE PRECISION array       User Workspace
       RWORK is not used by F04QAF, but is passed directly to
       routine APROD and may be used to pass information to that
       routine.

  21:  LRWORK -- INTEGER                                      Input
       On entry: the length of the array RWORK as declared in the
       (sub)program from which F04QAF is called. Constraint: LRWORK
```

>= 1.

22: IWORK(LIWORK) -- INTEGER array User Workspace
IWORK is not used by F04QAF, but is passed directly to routine APROD and may be used to pass information to that routine.

23: LIWORK -- INTEGER Input
On entry: the length of the array IWORK as declared in the (sub)program from which F04QAF is called. Constraint: LIWORK >= 1.

24: INFORM -- INTEGER Output
On exit: the reason for termination of F04QAF as follows:

INFORM = 0
The exact solution is x=0. No iterations are performed in this case.

INFORM = 1
The termination criterion of equation (3.6) has been satisfied with tol_1 and tol_2 as the values supplied in ATOL and BTOL respectively.

INFORM = 2
The termination criterion of equation (3.7) has been satisfied with tol_1 as the value supplied in ATOL.

INFORM = 3
The termination criterion of equation (3.6) has been satisfied with tol_1 and/or tol_2 as the value (epsilon), where (epsilon) is the machine precision. One or both of the values supplied in ATOL and BTOL must have been less than (epsilon) and was too small for this machine.

INFORM = 4
The termination criterion of equation (3.7) has been satisfied with tol_1 as the value (epsilon), where (epsilon) is the machine precision. The value supplied in ATOL must have been less than (epsilon) and was too small for this machine.

The values INFORM = 5, INFORM = 6 and INFORM = 7 correspond to failure with IFAIL = 2, IFAIL = 3 and IFAIL = 4 respectively (see Section 6) and when IFAIL is negative INFORM will be set to the same negative value.

25: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

5.1. Description of the printed output

When MSGLVL > 0, then F04QAF will produce output (except in the case where the routine fails with IFAIL = 1) on the advisory message channel (see X04ABF).

When MSGLVL >= 2 then a summary line is printed periodically giving the following information:

Output	Meaning
ITN	Iteration number, k.
X(1)	The first element of the current iterate x_k.
FUNCTION	The current value of the function, (rho), being minimized.
COMPAT	An estimate of $\|\|r_k\|\|/\|\|b\|\|$, where r_k is the residual corresponding to x_k. This value should converge to zero (in theory) if and only if the problem is compatible. COMPAT decreases monotonically.
INCOMPAT	An estimate of $\|\|A^T r_k\|\|/(\|\|A\|\|\|\|r_k\|\|)$ which should converge to zero if and only if at the solution (rho) is non-zero. INCOMPAT is not usually monotonic.
NRM(ABAR)	A monotonically increasing estimate of $\|\|A\|\|$.
COND(ABAR)	A monotonically increasing estimate of the

```
                condition number cond(A).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL< 0
     A negative value of IFAIL indicates an exit from F04QAF
     because the user has set MODE negative in APROD. The value
     of IFAIL will be the same as the user's setting of MODE.

IFAIL= 1
     On entry M < 1,

     or       N < 1,

     or       LRWORK < 1,

     or       LIWORK < 1.

IFAIL= 2
     The condition of equation (3.8) has been satisfied for the
     value of c    supplied in CONLIM. If this failure is
               lim
     unexpected the user should check that APROD is working
     correctly. Although conditions (3.6) or (3.7) have not been
     satisfied, the values returned in RNORM, ARNORM and XNORM
     may nevertheless indicate that an acceptable solution has
     been reached.

IFAIL= 3
     The conditions of equation (3.8) has been satisified for the
     value c   =1.0/(epsilon), where (epsilon) is the machine
            lim

     precision. The matrix A is nearly singular or rank deficient
     and the problem is too ill-conditioned for this machine. If
     this failure is unexpected, the user should check that APROD
     is working correctly.

IFAIL= 4
     The limit on the number of iterations has been reached. The
     number of iterations required by F04QAF and the condition of

     the matrix A can depend strongly on the scaling of the
     problem. Poor scaling of the rows and columns of A should be
     avoided whenever possible.
```

7. Accuracy

When the problem is compatible, the computed solution x will satisfy the equation

$$r=b-Ax,$$

where an estimate of $||r||$ is returned in the parameter RNORM. When the problem is incompatible, the computed solution x will satisfy the equation

$$A^T r=e,$$

where an estimate of $||e||$ is returned in the parameter ARNORM. See also Section 6.2 of Paige and Saunders [1].

8. Further Comments

The time taken by the routine is likely to be principally determined by the time taken in APROD, which is called twice on each iteration, once with MODE = 1 and once with MODE = 2. The time taken per iteration by the remaining operations in F04QAF is approximately proportional to max(m,n).

The Lanczos process will usually converge more quickly if A is pre-conditioned by a non-singular matrix M that approximates A in some sense and is also chosen so that equations of the form My=c can efficiently be solved for y. Some discussion of pre-conditioning in the context of symmetric matrices is given in Section 3 of the document for F04MBF. In the context of F04QAF, problem (3.1) is equivalent to

$$(AM^{-1})y=b, \quad Mx=y$$

and problem (3.2) is equivalent to minimizing

$$\rho=||r||, \quad r=b-(AM^{-1})y, \quad Mx=y.$$

Note that the normal matrix $(AM^{-1})^T(AM^{-1})=M^{-T}(A^TA)M^{-1}$ so that the pre-conditioning AM^{-1} is equivalent to the pre-conditioning $M^{-T}(A^TA)M^{-1}$ of the normal matrix A^TA.

Pre-conditioning can be incorporated into F04QAF simply by coding the routine APROD to compute $y+AM^{-1}x$ and $x+M^{-T}A^{T}y$ in place of $y+Ax$ and $x+A^{T}y$ respectively, and then solving the equations $Mx=y$ for x on return from F04QAF. $y+AM^{-1}x$ should be computed by solving $Mz=x$ for z and then computing $y+Az$, and $x+M^{-T}A^{T}y$ should be computed by solving $M^{T}z=A^{T}y$ for z and then forming $x+z$.

9. Example

To solve the linear least-squares problem

$$\text{minimize } (rho)=||r||, \quad r=b-Ax$$

where A is the 13 by 12 matrix and b is the 13 element vector given by

$$A=\begin{pmatrix} 1 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -1 & 0 & -1 & 4 & -1 & 0 & 0 & -1 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & -1 & 4 & -1 & 0 & 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & -1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 & 0 & -1 & 4 & -1 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & -1 & 0 & 0 & -1 & 4 & -1 & 0 & -1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 1 \\ 1 & 1 & 1 & 0 & 0 & 1 & 1 & 0 & 0 & 1 & 1 & 1 \end{pmatrix},$$

$$b=-h^{2}\begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \\ 1 \\ 0 \\ 0 \\ 1 \\ 1 \\ 0 \\ 0 \\ 0 \\ -h^{-3} \end{pmatrix}$$

with h=0.1.

```
          Such a problem can arise by considering the Neumann problem on a
          rectangle

                                    (delta)u
                                    --------=0
                                    (delta)n

               (delta)u           2            (delta)u      /
               --------=0  (nabla) u=g(x,y)    --------=0    |u=1
               (delta)n                        (delta)n      /
                                                             c

                                    (delta)u
                                    --------=0
                                    (delta)n

          where C is the boundary of the rectangle, and discretising as
          illustrated below with the square mesh

                   Please see figure in printed Reference Manual

          The 12 by 12 symmetric part of A represents the difference
          equations and the final row comes from the normalising condition.
          The example program has g(x,y)=1 at all the internal mesh points,
          but apart from this is written in a general manner so that the
          number of rows (NROWS) and columns (NCOLS) in the grid can
          readily be altered.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

          4.4.   The Level-3 Matrix-matrix Routines

          1. Scope of the Chapter
```

This Chapter is concerned with basic linear algebra routines which perform elementary algebraic operations involving scalars, vectors and matrices.

2. Background to the Problems

All the routines in this Chapter meet the specification of the Basic Linear Algebra Subprograms (BLAS) as described in Lawson et al [6], Dongarra et al [3] and [4]. The first reference describes a set of routines concerned with operations on scalars and vectors: these will be referred to here as the Level-0 and the Level-1 BLAS; the second reference describes a set of routines concerned with matrix-vector operations: these will be referred to here as the Level-2 BLAS; and the third reference describes a set of routines concerned with matrix-matrix operations: these will be referred to here as the Level-3 BLAS. The terminology reflects the number of operations involved. For example, a Level-2 routine involves $0(n^2)$ operations for an n by n matrix.

Table 1.1 indicates the naming scheme for the routines in this Chapter. The heading 'mixed type' is for routines where a mixture of data types is involved, such as a routine that returns the real Euclidean length of a complex vector.

		Level-0	Level-1	Level-2	Level-3
'real'	BLAS routine	F06A F	F06E F	F06P F	F06Y F
'complex'	BLAS routine	-	F06G F	F06S F	F06Z F

Table 1.1

The routines in this chapter do not have full routine documents, but instead are covered by some relevant background material, in Section 2.2, together with general descriptions, in Section 4, sufficient to enable their use. As this chapter is concerned only with basic linear algebra operations, the routines will not normally be required by the general user. The functionality of each routine is indicated in Section 3 so that those users requiring these routines to build specialist linear algebra modules can determine which routines are of interest.

2.1. The Use of BLAS Names

Many of the routines in other chapters of the Library call the BLAS in this chapter. These routines are usually called by the BLAS name and so, for correct operation of the Library, it is essential that users do not attempt to link their own versions of these routines. If users are in any doubt about how to avoid this, please consult your local support staff or the NAG Response Centre.

The BLAS names are used in order to make use of efficient implementations of the routines when these exist. Such implementations are stringently tested before being used, to ensure that they correctly meet the specification of the BLAS, and that they return the desired accuracy (see, for example, Dongarra et al. [3] and [4]).

2.2. Background Information

Most of the routines in this chapter implement straightforward scalar, vector and matrix operations that need no further explanation beyond a statement of the purpose of the routine. In this section we give some additional background information for those few cases where additional explanation may be necessary.

2.2.1. Real plane rotations

Two routines in the chapter are concerned with setting up and applying plane rotations. For further background information see Golub and Van Loan [5].

A plane rotation matrix for the (i,j) plane, R_{ij}, is an orthogonal matrix that is different from the unit matrix only in the elements r_{ii}, r_{jj}, r_{ij} and r_{ji}. If we put

$$R=\begin{pmatrix} r_{ii} & r_{ij} \\ r_{ji} & r_{jj} \end{pmatrix},$$

then, in the real case, it is usual to choose R_{ij} so that

$$R=\begin{pmatrix} c & s \\ -s & c \end{pmatrix}, \quad c=\cos(\theta), \quad s=\sin(\theta). \qquad (2.1)$$

The application of plane rotations is straightforward and needs no further elaboration, so further comment is made only on the construction of plane rotations.

The most common use of plane rotations is to choose c and s so that for given a and b,

```
                    ( c s)(a) (d)
                    (-s c)(b)=(0)                        (2.2)
```

In such an application the matrix R is often termed a Givens rotation matrix.

The BLAS routine F06AAF(*) (DROTG), see Lawson et al [6] and Dodson and Grimes [1, 2], computes c, s and d as

```
                                2  2 1/2
                      d=(sigma)(a +b )   ,
                {a/d, d/=0       {b/d, d/=0
              c={1,   d=0 ,    s={0,   d=0               (2.3)

              {sign a,|a|>|b|
where (sigma)={sign b,|a|<=|b|.
```

The value z defined as

```
                     {s,   |s|<c or c=0
                   z={1/c, 0<|c|<=s                      (2.4)
```

is also computed and this enables c and s to be reconstructed from the single value z as

```
               {0,          z=1
               {    2 1/2              {1,       z=1
             c={(1-z )    , |z|<1    s={z,       |z|<1
               {1/z,        |z|>1,     {    2
                                       {(1-c ), |z|>1.
```

3. Recommendations on Choice and Use of Routines

This section lists the routines in each of the categories Level-0 (scalar), Level-1 (vector), Level-2 (matrix-vector and matrix) and Level-3 (matrix-matrix). The corresponding double precision BLAS name is indicated in brackets.

Within each section routines are listed in alphabetic order of the fifth character in the routine name, so that corresponding real and complex routines may have adjacent entries.

3.1. The Level-0 Scalar Routine

The Level-0 routine performs the scalar operation of generating a plane rotation.

F06AAF (DROTG)	generates a real plane rotation.

3.2. The Level-1 Vector Routines

The Level-1 routines perform operations on or between vectors, such as computing dot products and Euclidean lengths.

F06EAF (DDOT)	computes the dot product of two real vectors
F06GAF (ZDOTU)	computes the dot product of two complex vectors (unconjugated)
F06GBF (ZDOTC)	computes the dot product of two complex vectors (conjugated)
F06ECF (DAXPY)	adds a scalar times a vector to another real vector
F06GCF (ZAXPY)	adds a scalar times a vector to another complex vector
F06EDF (DSCAL)	multiplies a real vector by a scalar
F06GDF (ZSCAL)	multiplies a complex vector by a scalar

```
F06JDF (ZDSCAL) multiplies a complex vector by a real scalar

F06EFF (DCOPY)  copies a real vector

F06GFF (ZCOPY)  copies a complex vector

F06EGF (DSWAP)  swaps two real vectors

F06GGF (ZSWAP)  swaps two complex vectors

F06EJF (DNRM2)  computes the Euclidean length of a real vector

F06JJF (DZNRM2) computes the Euclidean length of a complex vector

F06EKF (DASUM)  sums the absolute values of the elements of a
                real vector

F06JKF (DZASUM) sums the absolute values of the elements of a
                complex vector

F06JLF (IDAMAX) finds the index of the element of largest
                absolute value of a real vector

F06JMF (IZAMAX) finds the index of the element of largest
                absolute value of a complex vector

F06EPF (DROT)   applies a real plane rotation

3.3. The Level-2 Matrix-vector Routines

The Level-2 routines perform matrix-vector operations, such as
forming the product between a matrix and a vector.

F06PAF (DGEMV)  computes a matrix-vector product;
                real general matrix

F06SAF (ZGEMV)  computes a matrix-vector product;
                complex general matrix

F06PBF (DGBMV)  computes a matrix-vector product;
                real general band matrix

F06SBF (ZGBMV)  computes a matrix-vector product;
                complex general band matrix

F06PCF (DSYMV)  computes a matrix-vector product;
                real symmetric matrix

F06SCF (ZHEMV)  computes a matrix-vector product;
                complex Hermitian matrix
```

F06PDF (DSBMV)	computes a matrix-vector product; real symmetric band matrix
F06SDF (ZHBMV)	computes a matrix-vector product; complex Hermitian band matrix
F06PEF (DSPMV)	computes a matrix-vector product; real symmetric packed matrix
F06SEF (ZHPMV)	computes a matrix-vector product; complex Hermitian packed matrix
F06PFF (DTRMV)	computes a matrix-vector product; real triangular matrix
F06SFF (ZTRMV)	computes a matrix-vector product; complex triangular matrix
F06PGF (DTBMV)	computes a matrix-vector product; real triangular band matrix
F06SGF (ZTBMV)	computes a matrix-vector product; complex triangular band matrix
F06PHF (DTPMV)	computes a matrix-vector product; real triangular packed matrix
F06SHF (ZTPMV)	computes a matrix-vector product; complex triangular packed matrix
F06PJF (DTRSV)	solves a system of equations; real triangular coefficient matrix
F06SJF (ZTRSV)	solves a system of equations; complex triangular coefficient matrix
F06PKF (DTBSV)	solves a system of equations; real triangular band coefficient matrix
F06SKF (ZTBSV)	solves a system of equations; complex triangular band coefficient matrix
F06PLF (DTPSV)	solves a system of equations; real triangular packed coefficient matrix
F06SLF (ZTPSV)	solves a system of equations; complex triangular packed coefficient matrix
F06PMF (DGER)	performs a rank-one update;

```
                real general matrix

F06SMF (ZGERU)  performs a rank-one update;
                complex general matrix (unconjugated vector)

F06SNF (ZGERC)  performs a rank-one update;
                complex general matrix (conjugated vector)

F06PPF (DSYR)   performs a rank-one update;
                real symmetric matrix

F06SPF (ZHER)   performs a rank-one update;
                complex Hermitian matrix

F06PQF (DSPR)   performs a rank-one update;
                real symmetric packed matrix

F06SQF (ZHPR)   performs a rank-one update;
                complex Hermitian packed matrix

F06PRF (DSYR2)  performs a rank-two update;
                real symmetric matrix

F06SRF (ZHER2)  performs a rank-two update;
                complex Hermitian matrix

F06PSF (DSPR2)  performs a rank-two update;
                real symmetric packed matrix

F06SSF (ZHPR2)  performs a rank-two update;
                complex Hermitian packed matrix

3.4. The Level-3 Matrix-matrix Routines

The Level-3 routines perform matrix-matrix operations, such as
forming the product of two matrices.

F06YAF (DGEMM)  computes a matrix-matrix product; two real
                rectangular matrices

F06ZAF (ZGEMM)  computes a matrix-matrix product; two complex
                rectangular matrices

F06YCF (DSYMM)  computes a matrix-matrix product; one real
                symmetric matrix, one real rectangular matrix

F06ZCF (ZHEMM)  computes a matrix-matrix product; one complex
                Hermitian matrix, one complex rectangular matrix

F06YFF (DTRMM)  computes a matrix-matrix product; one real
```

	triangular matrix, one real rectangular matrix
F06ZFF (ZTRMM)	computes a matrix-matrix product; one complex triangular matrix, one complex rectangular matrix
F06YJF (DTRSM)	solves a system of equations with multiple right-hand sides, real triangular coefficient matrix
F06ZJF (ZTRSM)	solves a system of equations with multiple right-hand sides, complex triangular coefficient matrix
F06YPF (DSYRK)	performs a rank-k update of a real symmetric matrix
F06ZPF (ZHERK)	performs a rank-k update of a complex hermitian matrix
F06YRF (DSYR2K)	performs a rank-2k update of a real symmetric matrix
F06ZRF (ZHER2K)	performs a rank-2k update of a complex Hermitian matrix
F06ZTF (ZSYMM)	computes a matrix-matrix product: one complex symmetric matrix, one complex rectangular matrix
F06ZUF (ZSYRK)	performs a rank-k update of a complex symmetric matrix
F06ZWF (ZSYR2K)	performs a rank-2k update of a complex symmetric matrix

4. Description of the F06 Routines

In this section we describe the purpose of each routine and give information on the parameter lists, where appropriate indicating their general nature. Usually the association between the routine arguments and the mathematical variables is obvious and in such cases a description of the argument is omitted.

Within each section, the parameter lists for all routines are presented, followed by the purpose of the routines and information on the parameter lists. The double precision BLAS names are given in ENTRY statements.

Within each section routines are listed in alphabetic order of the fifth character in the routine name, so that corresponding real and complex routines may have adjacent entries.

4.1. The Level-0 Scalar Routines

The scalar routines have no array arguments.

```
SUBROUTINE   F06AAF( A,B,C,S )
ENTRY        DROTG ( A,B,C,S )
DOUBLE PRECISION     A,B,C,S
```

F06AAF(*) generates the parameters c and s of a Givens rotation as defined by equations (2.3) and (2.4), from given a and b. On exit, A is overwritten by d and B is overwritten by z.

4.2. The Level-1 Vector Routines

The vector routines all have one or more one-dimensional arrays as arguments, each representing a vector.

The length of each vector, n, is represented by the argument N, and the routines may be called with non-positive values of N, in which case the routine returns immediately except for the functions, which set the function value to zero before returning.

In addition to the argument N, each array argument is also associated with an increment argument that immediately follows the array argument, and whose name consists of the three characters INC, followed by the name of the array. For example, a vector x will be represented by the two arguments X, INCX. The increment argument is the spacing (stride) in the array for which the elements of the vector occur. For instance, if INCX = 2, then the elements of x are in locations X(1),X(3),...,X(2*N-1) of the array X and the intermediate locations X(2),X(4),...,X(2*N-2) are not referenced.

Thus when INCX > 0, the vector element x_i is in the array element X(1+(i-1)*INCX). When INCX <= 0 the elements are stored in the reverse order so that the vector element x_i is in the array element X(1-(n-i)*INCX) and hence, in particular, the element x_n is in X(1). The declared length of the array X in the calling (sub)program must be at least (1+(N-1)*|INCX|).

Non-positive increments are permitted only for those routines that have more than one array argument. While zero increments are formally permitted for such routines, their use in Chapter F06 is strongly discouraged since the effect may be implementation dependent.

```
DOUBLE PRECISION FUNCTION F06EAF ( N,      X,INCX,Y,INCY )

```

```
SUBROUTINE                F06EPF ( N,      X,INCX,Y,INCY,C,S )
ENTRY                     DROT   ( N,      X,INCX,Y,INCY,C,S )
INTEGER                            N,        INCX,  INCY
DOUBLE PRECISION                           X(*),  Y(*),  C,S
```

F06EAF(*) and F06GAF(*)

return the dot product x^Ty.

F06GBF(*)

returns the dot product x^Hy, where x^H denotes the complex conjugate of x^T.

F06ECF(*) and F06GCF(*)

perform the operation y<-(alpha)x+y, often called an axpy operation.

F06EDF(*), F06GDF(*) and F06JDF(*)

perform the operation x<-(alpha)x.

F06EFF(*) and F06GFF(*)

perform the operation y<-x.

F06EGF(*) and F06GGF(*)

perform the operation x<=>y, that is x and y are swapped.

F06EJF(*) and F06JJF(*)

return the value $||x||_2$ defined by $||x||_2 = \left(\sum_{i=1}^{n} |x_i|^2 \right)^{1/2}$.

F06EKF(*)

returns the value $||x||_1$ defined by $||x||_1 = \sum_{i=1}^{n} |x_i|$.

F06JKF(*)

returns the value asum defined by asum= $\sum_{i=1}^{n}(|Re(x_i)|+|Im(x_i)|)$.

F06JLF(*)

returns the first index j such that $|x_j|=\max_i |x_i|$.

F06JMF(*)

returns the first index j such that
$|Re(x_j)|+|Im(x_j)|=\max_i (|Re(x_i)|+|Im(x_i)|)$.

F06EPF(*)

performs the plane rotation $\begin{pmatrix} x^T \\ y^T \end{pmatrix} \leftarrow \begin{pmatrix} c & s \\ -s & c \end{pmatrix}\begin{pmatrix} x^T \\ y^T \end{pmatrix}$.

4.3. The Level-2 Matrix-vector Routines

The matrix-vector routines all have one array argument representing a matrix; usually this is a two-dimensional array but in some cases the matrix is represented by a one-dimensional array.

The size of the matrix is determined by the arguments M and N for an m by n rectangular matrix; and by the argument N for an n by n symmetric, Hermitian, or triangular matrix. Note that it is permissible to call the routines with M or N = 0, in which case the routines exit immediately without referencing their array arguments. For band matrices, the bandwidth is determined by the arguments KL and KU for a rectangular matrix with kl sub-diagonals and ku super-diagonals; and by the argument K for a symmetric, Hermitian, or triangular matrix with k sub-diagonals and/or super-diagonals.

The description of the matrix consists either of the array name (A) followed by the first dimension of the array as declared in the calling (sub)program (LDA), when the matrix is being stored in a two-dimensional array; or the array name (AP) alone when the matrix is being stored as a (packed) vector. In the former case the actual array must contain at least ((n-1)d+l) elements, where d is the first dimension of the array, d>=l , and l=m for arrays representing general matrices, l=n for arrays representing symmetric, Hermitian and triangular matrices, l=kl+ku+1 for arrays representing general band matrices and l=k+1 for symmetric, Hermitian and triangular band matrices. For one-dimensional arrays representing matrices (packed storage) the actual array must contain at least $\frac{1}{2}n(n+1)$ elements.

As with the vector routines, vectors are represented by one-dimensional arrays together with a corresponding increment argument (see Section 4.2). The only difference is that for these routines a zero increment is not permitted.

When the vector x consists of k elements then the declared length of the array X in the calling (sub)program must be at least (1+(k-1)|INCX|).

The arguments that specify options are character arguments with the names TRANS, UPLO and DIAG. TRANS is used by the matrix-vector product routines as follows:

Value	Meaning
'N' or 'n'	Operate with the matrix
'T' or 't'	Operate with the transpose of the matrix
'C' or 'c'	Operate with the conjugate transpose of the matrix

In the real case the values 'T', 't', 'C' and 'c' have the same meaning.

UPLO is used by the Hermitian, symmetric, and triangular matrix routines to specify whether the upper or lower triangle is being referenced as follows:

Value	Meaning
'U' or 'u'	Upper triangle
'L' or 'l'	Lower triangle

DIAG is used by the triangular matrix routines to specify whether or not the matrix is unit triangular, as follows:

Value   Meaning

```
    'U' or 'u' Unit triangular

    'N' or 'n' Non-unit triangular

When DIAG is supplied as 'U' or 'u' the diagonal elements are not
referenced.

It is worth noting that actual character arguments in Fortran may
be longer than the corresponding dummy arguments. So that, for
example, the value 'T' for TRANS may be passed as 'TRANSPOSE'.

The routines for real symmetric and complex Hermitian matrices
allow for the matrix to be stored in either the upper (UPLO = 'U
to be packed in a one-dimensional array. In the latter case the
upper triangle may be packed sequentially column by column (UPLO
= 'U'), or the lower triangle may be packed sequentially column
by column (UPLO = 'L'). Note that for real symmetric matrices
packing the upper triangle by column is equivalent to packing the
lower triangle by rows, and packing the lower triangle by columns
is equivalent to packing the upper triangle by rows. (For complex
Hermitian matrices the only difference is that the off-diagonal
elements are conjugated.)

For triangular matrices the argument UPLO serves to define
whether the matrix is upper (UPLO = 'U') or lower (UPLO = 'L')
triangular. In packed storage the triangle has to be packed by
column.

The band matrix routines allow storage so that the jth column of
the matrix is stored in the jth column of the Fortran array. For
a general band matrix the diagonal of the matrix is stored in the
(ku+1)th row of the array. For a Hermitian or symmetric matrix
either the upper triangle (UPLO = 'U') may be stored in which
case the leading diagonal is in the (k+1)th row of the array, or
the lower triangle (UPLO = 'L') may be stored in which case the
leading diagonal is in the first row of the array. For an upper
triangular band matrix (UPLO = 'U') the leading diagonal is in
the (k+1)th row of the array and for a lower triangular band
matrix (UPLO = 'L') the leading diagonal is in the first row.

For a Hermitian matrix the imaginary parts of the diagonal
elements are of course zero and thus the imaginary parts of the
corresponding Fortran array elements need not be set, but are
assumed to be zero.

For packed triangular matrices the same storage layout is used
whether or not DIAG = 'U', i.e., space is left for the diagonal
elements even if those array elements are not referenced.

F06SHF(*), and is a triangular band matrix for F06PGF(*) and
F06SGF(*).

F06PJF(*), F06SJF(*), F06PLF(*), F06SLF(*), F06PKF(*) and
F06SKF(*)
```

```
solve the equations

    Ax=b,        when TRANS = 'N',

     T
    A x=b,       when TRANS = 'T',

     H
    A x=b,       when TRANS = 'C',

where A is a triangular matrix for F06PJF(*) and F06SJF(*), is a
triangular matrix stored in packed form for F06PLF(*) and
F06SLF(*), and is a triangular band matrix for F06PKF(*) and
F06SKF(*). The vector b must be supplied in the array X and is
overwritten by the solution. It is important to note that no test
for singularity is included in these routines.

F06PMF(*) and F06SMF(*)

                                  T
perform the operation A<-(alpha)xy +A, where A is a general
matrix.

F06SNF(*)

                                   H
performs the operation A<-(alpha)xy +A, where A is a general
complex matrix.

F06PPF(*) and F06PQF(*)

                                  T
perform the operation A<-(alpha)xx +A, where A is a symmetric
matrix for F06PPF(*) and is a symmetric matrix stored in packed
form for F06PQF(*).

F06SPF(*) and F06SQF(*)

                                  H
perform the operation A<-(alpha)xx +A, where A is an Hermitian
matrix for F06SPF(*) and is an Hermitian matrix stored in packed
form for F06SQF(*).

F06PRF(*) and F06PSF(*)

                                  T          T
perform the operation A<-(alpha)xy +(alpha)yx +A, where A is a
symmetric matrix for F06PRF(*) and is a symmetric matrix stored
in packed form for F06PSF(*).
```

F06SRF(*) and F06SSF(*)

perform the operation $A<-(alpha)xy^{H}+(alpha)yx^{H}+A$, where A is an Hermitian matrix for F06SRF(*) and is an Hermitian matrix stored in packed form for F06SSF(*).

The following argument values are invalid:

Any value of the character arguments DIAG, TRANS, or UPLO whose meaning is not specified.

M < 0

N < 0

KL < 0

KU < 0

K < 0

LDA < M

LDA < KL + KU + 1

LDA < N for the routines involving full Hermitian, symmetric or triangular matrices

LDA < K + 1 for the routines involving band Hermitian, symmetric or triangular matrices

INCX = 0

INCY = 0

If a routine is called with an invalid value then an error message is output, on the error message unit (see X04AAF), giving the name of the routine and the number of the first invalid argument, and execution is terminated.

4.4. The Level-3 Matrix-matrix Routines

The matrix-matrix routines all have either two or three arguments representing a matrix, one of which is an input-output argument, and in each case the arguments are two-dimensional arrays.

The sizes of the matrices are determined by one or more of the arguments M, N and K. The size of the input-output array is always determined by the arguments M and N for a rectangular m by n matrix, and by the argument N for a square n by n matrix. It is permissible to call the routines with M or N = 0, in which case the routines exit immediately without referencing their array arguments.

Many of the routines perform an operation of the form

C<-P+(beta)C,

where P is the product of two matrices, or the sum of two such products. When the inner dimension of the matrix product is different from m or n it is denoted by K. Again it is permissible to call the routines with K = 0 and if M > 0, but K = 0, then the routines perform the operation

C<-(beta)C.

As with the Level-2 routines (see Section 4.3) the description of the matrix consists of the array name (A or B or C) followed by the first dimension (LDA or LDB or LDC).

The arguments that specify options are character arguments with the names SIDE, TRANSA, TRANSB, TRANS, UPLO and DIAG. UPLO and DIAG have the same values and meanings as for the Level-2 routines (see Section 4.3); TRANSA, TRANSB and TRANS have the same values and meanings as TRANS in the Level-2 routines, where TRANSA and TRANSB apply to the matrices A and B respectively. SIDE is used by the routines as follows:

Value	Meaning
'L'	Multiply general matrix by symmetric, Hermitian or triangular matrix on the left
'R'	Multiply general matrix by symmetric, Hermitian or triangular matrix on the right

The storage conventions for matrices are as for the Level-2 routines (see Section 4.3).

SIDE='R'  XA=(alpha)B        XA =(alpha)B       XA =(alpha)B

          A is               A is               A is
          triangular         triangular         triangular
          n*n                n*n                n*n

where B is a general m by n matrix. The m by n solution matrix X
is overwritten on the array B. It is important to note that no
test for singularity is included in these routines.

F06YPF(*), F06ZPF(*) and F06ZUF(*) perform the operation
indicated in the following table:

          TRANS = 'N'        TRANS = 'T'        TRANS = 'C'

                        T                  T                  T
F06YPF    C <- (alpha)AA     C <- (alpha)A A    C <- (alpha)A A
              +(beta)C           +(beta)C           +(beta)C
                        T                  T
F06ZUF    C <- (alpha)AA     C <- (alpha)A A         --
              +(beta)C           +(beta)C
                        H                                     H
F06ZPF    C <- (alpha)AA          --            C <- (alpha)A A
              +(beta)C                              +(beta)C

          A is n*k           A is k*n           A is k*n

where A is a general matrix and C is an n by n symmetric matrix
for F06YPF(*) and F06ZUF(*), and is an n by n Hermitian matrix
for F06ZPF(*).

F06YRF(*), F06ZRF(*) and F06ZWF(*) perform the operation
indicated in the following table:

          TRANS = 'N'        TRANS = 'T'        TRANS = 'C'
```

```
                        T                 T                  T
F06YRF    C <- (alpha)AB     C <- (alpha)A B    C <- (alpha)A B
                        T                 T                  T
              +(alpha)BA         +(alpha)B A        +(alpha)B A
              +(beta)C           +(beta)C           +(beta)C
                        T                 T
F06ZWF    C <- (alpha)AB     C <- (alpha)A B           --
                        T                 T
              +(alpha)BA         +(alpha)B A
              +(beta)C           +(beta)C
                        H                                    H
F06ZRF    C <- (alpha)AB           --           C <- (alpha)A B
                        H                                    H
              +(alpha)BA                            +(alpha)B A
              +(beta)C                              +(beta)C

          A and B are n*k    A and B are k*n    A and B are k*n
```

where A and B are general matrices and C is an n by n symmetric
matrix for F06YRF(*) and F06ZWF(*), and is an n by n Hermitian
matrix for F06ZPF(*).

The following values of arguments are invalid:

Any value of the character arguments SIDE, TRANSA, TRANSB,
TRANS, UPLO or DIAG, whose meaning is not specified.

M < 0

N < 0

K < 0

LDA < the number of rows in the matrix A.

LDB < the number of rows in the matrix B.

LDC < the number of rows in the matrix C.

If a routine is called with an invalid value then an error
message is output, on the error message unit (see X04AAF), giving
the name of the routine and the number of the first invalid
argument, and execution is terminated.

     F07(3NAG)        Foundation Library (12/10/92)        F07(3NAG)

          F07 -- Linear Equations (LAPACK)              Introduction -- F07
                                   Chapter F07
                            Linear Equations (LAPACK)

          1. Scope of the Chapter

          This chapter provides four routines concerned with matrix
          factorization, and the solution of systems of linear equations
          following the matrix factorizations.

          2. Background to the Problems

          Background material, together with pointers to the routines in
          this chapter, are to be found in the F01 and F04 Chapter
          Introductions.
          3. Recommendations on Choice and Use of Routines

          The routines in this chapter are derived from the LAPACK project
          and may also be called using the LAPACK name, which is given in
          brackets following the F07 name in the following descriptions.

          Routine F07ADF (DGETRF) performs an LU factorization of a real m
          by n matrix A. Following the use of this routine, F07AEF (DGETRS)
          may be used to solve a system of n non-singular linear equations,
          with one or more right-hand sides.

          Routine F07FDF (DPOTRF) performs the Cholesky factorization of a
          real symmetric positive-definite matrix A. Following the use of
          this routine, F07FEF (DPOTRS) may be used to solve a system of
          symmetric positive-definite linear equations, with one or more
          right-hand sides.

     F07ADF(3NAG)      Foundation Library (12/10/92)      F07ADF(3NAG)

          F07 -- Linear Equations (LAPACK)                          F07ADF
                  F07ADF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F07ADF (DGETRF) computes the LU factorization of a real m by n
          matrix.

          2. Specification

                 SUBROUTINE F07ADF (M, N, A, LDA, IPIV, INFO)
                 ENTRY             M, N, A, LDA, IPIV, INFO
                 INTEGER           M, N, LDA, IPIV(*), INFO
                 DOUBLE PRECISION A(LDA,*)

          The ENTRY statement enables the routine to be called by its
          LAPACK name.

          3. Description

          This routine forms the LU factorization of a real m by n matrix A
          as A=PLU, where P is a permutation matrix, L is lower triangular
          with unit diagonal elements (lower trapezoidal if m>n) and U is
          upper triangular (upper trapezoidal if m<n). Usually A is square
          (m=n), and both L and U are triangular. The routine uses partial
          pivoting, with row interchanges.

          4. References

          [1]   Golub G H and Van Loan C F (1989) Matrix Computations (2nd
                Edition). Johns Hopkins University Press, Baltimore,
                Maryland.

          5. Parameters
```

```
 1:  M -- INTEGER                                          Input
     On entry: m, the number of rows of the matrix A.
     Constraint: M >= 0.

 2:  N -- INTEGER                                          Input
     On entry: n, the number of columns of the matrix A.
     Constraint: N >= 0.

 3:  A(LDA,*) -- DOUBLE PRECISION array             Input/Output
     Note: the second dimension of the array A must be at least
     max(1,N).
     On entry: the m by n matrix A. On exit: A is overwritten by
     the factors L and U; the unit diagonal elements of L are not
     stored.

 4:  LDA -- INTEGER                                        Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which F07ADF is called.
     Constraint: LDA >= max(1,M).

 5:  IPIV(*) -- INTEGER array                             Output
     Note: the dimension of the array IPIV must be at least
     max(1,min(M,N)).
     On exit: the pivot indices. Row i of the matrix A was
     interchanged with row IPIV(i) for i=1,2,...,min(m,n).

 6:  INFO -- INTEGER                                      Output
     On exit: INFO = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

INFO < 0
     If INFO = -i, the ith parameter has an illegal value. An
     explanatory message is output, and execution of the program
     is terminated.

INFO > 0
     If INFO = i, u   is exactly zero. The factorization has been
                   ii
     completed but the factor U is exactly singular, and division
     by zero will occur if it is subsequently used to solve a
                                                  -1
     system of linear equations or to compute A   .

7. Accuracy

The computed factors L and U are the exact factors of a perturbed
matrix A+E, where
```

```
                 |E|<=c(min(m,n))(epsilon)P|L||U|,

          c(n) is a modest linear function of n, and (epsilon) is the
          machine precision.

          8. Further Comments

          The total number of floating-point operations is approximately
           2 3                           1 2                   1 2
           -n  if m=n (the usual case),  -n (3m-n) if m>n and  -m (3n-m) if
           3                             3                     3
          m<n.

          A call to this routine with m=n may be followed by calls to the
          routines:

                                                 T
               F07AEF (DGETRS) to solve AX=B or A X=B;

               F07AGF (DGECON)(*) to estimate the condition number of A;

               F07AJF (DGETRI)(*) to compute the inverse of A.

          The complex analogue of this routine is F07ARF (ZGETRF)(*).

          9. Example

          To compute the LU factorization of the matrix A, where

                              ( 1.80  2.88  2.05 -0.89)
                              ( 5.25 -2.95 -0.95 -3.80)
                            A=( 1.58 -2.69 -2.90 -1.04).
                              (-1.11 -0.66 -0.59  0.80)

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

\begin{verbatim}

     F07AEF(3NAG)      Foundation Library (12/10/92)      F07AEF(3NAG)

          F07 -- Linear Equations (LAPACK)                          F07AEF
                  F07AEF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F07AEF (DGETRS) solves a real system of linear equations with
                                           T
          multiple right-hand sides, AX=B or A X=B, where A has been
          factorized by F07ADF (DGETRF).

          2. Specification

                 SUBROUTINE F07AEF (TRANS, N, NRHS, A, LDA, IPIV, B, LDB,
                1                   INFO)
                 ENTRY            TRANS, N, NRHS, A, LDA, IPIV, B, LDB, INFO
                 INTEGER          N, NRHS, LDA, IPIV(*), LDB, INFO
                 DOUBLE PRECISION A(LDA,*), B(LDB,*)
                 CHARACTER*1      TRANS

          The ENTRY statement enables the routine to be called by its
          LAPACK name.

          3. Description

                                                           T
          To solve a real system of linear equations AX=B or A X=B, this
          routine must be preceded by a call to F07ADF (DGETRF)which
          computes the LU factorization of A as A=PLU. The solution is
          computed by forward and backward substitution.
```

If TRANS = 'N', the solution is computed by solving PLY=B and then UX=Y.

If TRANS = 'T' or 'C', the solution is computed by solving $U^T Y=B$ and then $L^T P^T X=Y$.

4. References

[1] Golub G H and Van Loan C F (1989) Matrix Computations (2nd Edition). Johns Hopkins University Press, Baltimore, Maryland.

5. Parameters

```
 1:  TRANS -- CHARACTER*1                                   Input
     On entry: indicates the form of the equations as follows:
          if TRANS = 'N', then AX=B is solved for X;
```

if TRANS = 'T' or 'C', then $A^T X=B$ is solved for X.

```
      Constraint: TRANS = 'N', 'T' or 'C'.

 2:  N -- INTEGER                                           Input
     On entry: n, the order of the matrix A. Constraint: N >= 0.

 3:  NRHS -- INTEGER                                        Input
     On entry: r, the number of right-hand sides. Constraint:
     NRHS >= 0.

 4:  A(LDA,*) -- DOUBLE PRECISION array                     Input
     Note: the second dimension of the array A must be at least
     max(1,N).
     On entry: the LU factorization of A, as returned by F07ADF
     (DGETRF).

 5:  LDA -- INTEGER                                         Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which F07AEF is called.
     Constraint: LDA >= max(1,N).

 6:  IPIV(*) -- INTEGER array                               Input
     Note: the dimension of the array IPIV must be at least
     max(1,N).
     On entry: the pivot indices, as returned by F07ADF (DGETRF).

 7:  B(LDB,*) -- DOUBLE PRECISION array              Input/Output
     Note: the second dimension of the array B must be at least
     max(1,NRHS).
     On entry: the n by r right-hand side matrix B. On exit: the
     n by r solution matrix X.

 8:  LDB -- INTEGER                                        Input
     On entry:
     the first dimension of the array B as declared in the
     (sub)program from which F07AEF is called.
     Constraint: LDB >= max(1,N).

 9:  INFO -- INTEGER                                      Output
     On exit: INFO = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

INFO < 0
     If INFO = -i, the ith parameter has an illegal value. An
     explanatory message is output, and execution of the program
     is terminated.

7. Accuracy

For each right-hand side vector b, the computed solution x is the
exact solution of a perturbed system of equations (A+E)x=b, where

                  |E|<=c(n)(epsilon)P|L||U|,

c(n) is a modest linear function of n, and (epsilon) is the
machine precision.

   ^
If x is the true solution, then the computed solution x satisfies
a forward error bound of the form

                   ^
              ||x-x||
                     infty
              ------------ <= c(n)cond(A,x)(epsilon)
               ||x||
                    infty

                    -1
where cond(A,x)=|||A  ||A||x|||     /||x||      <=
                                infty      infty
            -1
cond(A)=|||A  ||A|||     <=(kappa)     (A). Note that cond(A,x)
                    infty         infty
                                                T
can be much smaller than cond(A), and cond(A ) can be much larger
```

```
          (or smaller) than cond(A).

          Forward and backward error bounds can be computed by calling
          F07AHF (DGERFS)(*), and an estimate for (kappa)     (A) can be
                                                         infty
          obtained by calling F07AGF (DGECON)(*) with NORM ='I'.

          8. Further Comments

          The total number of floating-point operations is approximately
            2
          2n r.

          This routine may be followed by a call to F07AHF (DGERFS)(*) to
          refine the solution and return an error estimate.

          The complex analogue of this routine is F07ASF (ZGETRS)(*).

          9. Example

          To solve the system of equations AX=B, where

                              ( 1.80  2.88  2.05 -0.89)
                              ( 5.25 -2.95 -0.95 -3.80)
                            A=( 1.58 -2.69 -2.90 -1.04)
                              (-1.11 -0.66 -0.59  0.80)

          and

                                   ( 9.52  18.47)
                                   (24.35   2.25)
                                 B=( 0.77 -13.28).
                                   (-6.22  -6.21)

          Here A is unsymmetric and must first be factorized by F07ADF
          (DGETRF)).

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

```
\begin{page}{manpageXXf07fdf}{NAG Documentation: f07fdf}
\beginscroll
\begin{verbatim}

     F07FDF(3NAG)      Foundation Library (12/10/92)      F07FDF(3NAG)

          F07 -- Linear Equations (LAPACK)                          F07FDF
                  F07FDF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F07FDF (DPOTRF) computes the Cholesky factorization of a real
          symmetric positive-definite matrix.

          2. Specification

                 SUBROUTINE F07FDF (UPLO, N, A, LDA, INFO)
                 ENTRY            UPLO, N, A, LDA, INFO
                 INTEGER          N, LDA, INFO
                 DOUBLE PRECISION A(LDA,*)
                 CHARACTER*1      UPLO

          The ENTRY statement enables the routine to be called by its
          LAPACK name.

          3. Description

          This routine forms the Cholesky factorization of a real symmetric
                                                T                        T
          positive-definite matrix A either as A=U U if UPLO = 'U' or A=LL
          if UPLO = 'L', where U is an upper triangular matrix and L is
          lower triangular.

          4. References

          [1]   Demmel J W (1989) On Floating-point Errors in Cholesky.
```

LAPACK Working Note No. 14. University of Tennessee, Knoxville.

[2] Golub G H and Van Loan C F (1989) Matrix Computations (2nd Edition). Johns Hopkins University Press, Baltimore, Maryland.

5. Parameters

1: UPLO -- CHARACTER*1 Input

On entry: indicates whether the upper or lower triangular part of A is stored and how A is factorized, as follows:

if UPLO = 'U', then the upper triangular part of A is stored and A is factorized as $U^T U$, where U is upper triangular;

if UPLO = 'L', then the lower triangular part of A is stored and A is factorized as LL^T, where L is lower triangular.

Constraint: UPLO = 'U' or 'L'.

2: N -- INTEGER Input

On entry: n, the order of the matrix A. Constraint: N >= 0.

3: A(LDA,*) -- DOUBLE PRECISION array Input/Output

Note: the second dimension of the array A must be at least max(1,N).
On entry: the n by n symmetric positive-definite matrix A. If UPLO = 'U', the upper triangle of A must be stored and the elements of the array below the diagonal are not referenced; if UPLO = 'L', the lower triangle of A must be stored and the elements of the array above the diagonal are not referenced. On exit: the upper or lower triangle of A is overwritten by the Cholesky factor U or L as specified by UPLO.

4: LDA -- INTEGER Input

On entry:
the first dimension of the array A as declared in the (sub)program from which F07FDF is called.
Constraint: LDA >= max(1,N).

5: INFO -- INTEGER Output

On exit: INFO = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

```
INFO < 0
     If INFO = -i, the ith parameter has an illegal value. An
     explanatory message is output, and execution of the program
     is terminated.

INFO > 0
     If INFO = i, the leading minor of order i is not positive-
     definite and the factorization could not be completed. Hence
     A itself is not positive-definite. This may indicate an
     error in forming the matrix A. To factorize a symmetric
     matrix which is not positive-definite, call F07MDF
     (DSYTRF)(*) instead.

7. Accuracy

If UPLO = 'U', the computed factor U is the exact factor of a
perturbed matrix A+E, where

                                        T
                  |E|<=c(n)(epsilon)|U ||U|,

c(n) is a modest linear function of n, and (epsilon) is the
machine precision. If UPLO = 'L', a similar statement holds for
the computed factor L. It follows that

|e  |<=c(n)(epsilon)  /a  a  .
  ij                \/  ii jj

8. Further Comments

The total number of floating-point operations is approximately
 1 3
 -n .
 3

A call to this routine may be followed by calls to the routines:

     F07FEF (DPOTRS) to solve AX=B;

     F07FGF (DPOCON)(*) to estimate the condition number of A;

     F07FJF (DPOTRI)(*) to compute the inverse of A.

The complex analogue of this routine is F07FRF (ZPOTRF)(*).

9. Example

To compute the Cholesky factorization of the matrix A, where
```

```
                         ( 4.16 -3.12  0.56 -0.10)
                         (-3.12  5.03 -0.83  1.18)
                       A=( 0.56 -0.83  0.76  0.34).
                         (-0.10  1.18  0.34  1.18)

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          F07FEF (DPOTRS) solves a real symmetric positive-definite system
          of linear equations with multiple right-hand sides, AX=B, where A
          has been factorized by F07FDF (DPOTRF).

          2. Specification

                 SUBROUTINE F07FEF (UPLO, N, NRHS, A, LDA, B, LDB, INFO)
                 ENTRY            UPLO, N, NRHS, A, LDA, B, LDB, INFO
```

```
      INTEGER          N, NRHS, LDA, LDB, INFO
      DOUBLE PRECISION A(LDA,*), B(LDB,*)
      CHARACTER*1      UPLO
```

The ENTRY statement enables the routine to be called by its LAPACK name.

3. Description

To solve a real symmetric positive-definite system of linear equations AX=B, this routine must be preceded by a call to F07FDF (DPOTRF) which computes the Cholesky factorization of A. The solution X is computed by forward and backward substitution.

If UPLO = 'U', $A=U^TU$, where U is upper triangular; the solution X is computed by solving $U^TY=B$ and then UX=Y.

If UPLO = 'L', $A=LL^T$, where L is lower triangular; the solution X is computed by solving LY=B and then $L^TX=Y$.

4. References

[1] Golub G H and Van Loan C F (1989) Matrix Computations (2nd Edition). Johns Hopkins University Press, Baltimore, Maryland.

5. Parameters

1: UPLO -- CHARACTER*1 Input
On entry: indicates whether the upper or lower triangular part of A is stored and how A is factorized, as follows:

if UPLO = 'U', then $A=U^TU$ where U is upper triangular;

if UPLO = 'L', then $A=LL^T$ where L is lower triangular.

Constraint: UPLO = 'U' or 'L'.

2: N -- INTEGER Input
On entry: n, the order of the matrix A. Constraint: N >= 0.

3: NRHS -- INTEGER Input
On entry: r, the number of right-hand sides. Constraint: NRHS >= 0.

4: A(LDA,*) -- DOUBLE PRECISION array Input

```
     Note: the second dimension of the array A must be at least
     max(1,N).
     On entry: the Cholesky factor of A, as returned by F07FDF
     (DPOTRF).

 5:  LDA -- INTEGER                                         Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which F07FEF is called.
     Constraint: LDA >=max(1,N).

 6:  B(LDB,*) -- DOUBLE PRECISION array              Input/Output
     Note: the second dimension of the array B must be at least
     max(1,NRHS).
     On entry: the n by r right-hand side matrix B.

 7:  LDB -- INTEGER                                         Input
     On entry:
     the first dimension of the array B as declared in the
     (sub)program from which F07FEF is called.
     Constraint: LDB >=max(1,N).

 8:  INFO -- INTEGER                                       Output
     On exit: INFO = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

INFO < 0
     If INFO = -i, the ith parameter has an illegal value. An
     explanatory message is output, and execution of the program
     is terminated.

7. Accuracy

For each right-hand side vector b, the computed solution x is the
exact solution of a perturbed system of equations (A+E)x=b, where

                         T
     |E|<=c(n)(epsilon)|U ||U| if UPLO = 'U',

                            T
     |E|<=c(n)(epsilon)|L||L | if UPLO = 'L',

c(n) is a modest linear function of n, and (epsilon) is the
machine precision.

   ^
If x is the true solution, then the computed solution x satisfies
a forward bound of the form
```

```
                 ^
             ||x-x||
                    infty
             ------------<=c(n)cond(A,x)(epsilon)
              ||x||
                   infty

                   -1
where cond(A,x)=|||A  ||A||x|||     /||x||      <=
                              infty      infty
            -1
cond(A)=|||A  ||A|||     <=(kappa)     (A). Note that cond(A,x)
                   infty         infty
can be much smaller than cond(A).
```

```
Forward and backward error bounds can be computed by calling
F07FHF (DPORFS)(*), and an estimate for (kappa)     (A) (
                                              infty
=(kappa) (A)) can be obtained by calling F07FGF (DPOCON)(*).
        1
```

8. Further Comments

```
The total number of floating-point operations is approximately
  2
2n r.
```

This routine may be followed by a call to F07FHF (DPORFS)(*) to refine the solution and return an error estimate.

The complex analogue of this routine is F07FSF (ZPOTRS)(*).

9. Example

To compute the Cholesky factorization of the matrix A, where

```
                    ( 4.16 -3.12  0.56 -0.10)
                    (-3.12  5.03 -0.83  1.18)
                  A=( 0.56 -0.83  0.76  0.34).
                    (-0.10  1.18  0.34  1.18)
```

and

```
                          (  8.70 8.30)
                          (-13.35 2.13)
                        B=(  1.89 1.61).
                          ( -4.14 5.00)
```

Here A is symmetric positive-definite and must first be

```
          factorized by F07FDF (DPOTRF).

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

     M01(3NAG)         Foundation Library (12/10/92)         M01(3NAG)

          M01 -- Sorting                                Introduction -- M01
                                    Chapter M01
                                      Sorting

          1. Scope of the Chapter

          This chapter is concerned with sorting numeric data. It handles
          only the simplest types of data structure and it is concerned
          only with internal sorting -- that is, sorting a set of data
          which can all be stored within the program.

          Users with large files of data or complex data structures to be
          sorted should use a comprehensive sorting program or package.

          2. Background to the Problems

          The usefulness of sorting is obvious (perhaps a little too
          obvious, since sorting can be expensive and is sometimes done
          when not strictly necessary). Sorting may traditionally be
          associated with data-processing and non-numerical programming,
          but it has many uses within the realm of numerical analysis, for
          example, to arrange eigenvalues in ascending order of absolute
          value and in the ranking of observations for nonparametric
          statistics.

          The general problem may be defined as follows. We are given N
          items of data
```

$$R_1, R_2, \ldots, R_N.$$

Each item R_i contains a key K_i which can be ordered relative to any other key according to some specified criterion (for example, ascending numeric value). The problem is to determine a permutation

$$p(1), p(2), \ldots, p(N)$$

which puts the keys in order:

$$K_{p(1)} <= K_{p(2)} <= \ldots <= K_{p(N)}$$

Sometimes we may wish actually to rearrange the items so that their keys are in order; for other purposes we may simply require a table of indices so that the items can be referred to in sorted order; or yet again we may require a table of ranks, that is, the positions of each item in the sorted order.

For example, given the single-character items, to be sorted into alphabetic order:

```
     E    B    A    D    C
```

the indices of the items in sorted order are

```
     3    2    5    4    1
```

and the ranks of the items are

```
     5    2    1    4    3
```

Indices may be converted to ranks, and vice versa, by simply computing the inverse permutation.

The items may consist solely of the key (each item may simply be a number). On the other hand, the items may contain additional information (for example, each item may be an eigenvalue of a matrix and its associated eigenvector, the eigenvalue being the key). In the latter case there may be many distinct items with equal keys, and it may be important to preserve the original order among them (if this is achieved, the sorting is called ' stable').

There are a number of ingenious algorithms for sorting. For a fascinating discussion of them, and of the whole subject, see Knuth [1].

2.1. References

[1] Knuth D E (1973) The Art of Computer Programming, Vol 3. Addison-Wesley.

3. Recommendations on Choice and Use of Routines

Four categories of routines are provided:

- routines which rearrange the data into sorted order (M01C-);

- routines which determine the ranks of the data, leaving the data unchanged (M01D-);

- routines which rearrange the data according to pre-determined ranks (M01E-);

- service routines (M01Z-).

Routines are provided for sorting double precision data only.

If the task is simply to rearrange a one-dimensional array of data into sorted order, then M01CAF should be used, since this requires no extra workspace and is faster than any other method.

For many applications it is in fact preferable to separate the task of determining the sorted order (ranking) from the task of rearranging data into a pre-determined order; the latter task may not need to be performed at all. Frequently it may be sufficient to refer to the data in sorted order via an index vector, without rearranging it. Frequently also one set of data (e.g. a column of a matrix) is used for determining a set of ranks, which are then applied to other data (e.g. the remaining columns of the matrix).

To determine the ranks of a set of data, use an M01D- routine. Routines are provided for ranking one-dimensional arrays, and for ranking rows or columns of two-dimensional arrays.

To create an index vector so that data can be referred to in sorted order, first call an M01D- routine to determine the ranks, and then call M01ZAF to convert the vector of ranks into an index vector.

To rearrange data according to pre-determined ranks: use M01EAF if the data is stored in a one-dimensional array; or if the data is stored in a more complicated structure, use an index vector to

```
          generate a new copy of the data in the desired order.

          Examples of these operations can be found in the routine
          documents of the relevant routines.

          4. Index

           Ranking:
               columns of a matrix, double precision numbers         M01DJF
               rows of a matrix, double precision numbers            M01DEF
               vector, double precision numbers                      M01DAF
          Rearranging (according to pre-determined ranks):
               vector, double precision numbers                      M01EAF
          Service routines:
               invert a permutation (ranks to indices or vice        M01ZAF
               versa)
          Sorting (i.e., rearranging into sorted order):
               vector, double precision numbers                      M01CAF

          M01 -- Sorting                                    Contents -- M01
          Chapter M01

          Sorting

          M01CAF  Sort a vector, double precision numbers

          M01DAF  Rank a vector, double precision numbers

          M01DEF  Rank rows of a matrix, double precision numbers

          M01DJF  Rank columns of a matrix, double precision numbers

          M01EAF  Rearrange a vector according to given ranks, double
                  precision numbers

          M01ZAF  Invert a permutation

\begin{page}{manpageXXm01caf}{NAG Documentation: m01caf}
\beginscroll
\begin{verbatim}

     M01CAF(3NAG)      Foundation Library (12/10/92)      M01CAF(3NAG)

          M01 -- Sorting                                            M01CAF
                  M01CAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          M01CAF rearranges a vector of double precision numbers into
          ascending or descending order.

          2. Specification

                 SUBROUTINE M01CAF (RV, M1, M2, ORDER, IFAIL)
                 INTEGER          M1, M2, IFAIL
                 DOUBLE PRECISION RV(M2)
                 CHARACTER*1      ORDER

          3. Description

          M01CAF is based on Singleton's implementation of the 'median-of-
          three' Quicksort algorithm [2], but with two additional
          modifications. First, small subfiles are sorted by an insertion
          sort on a separate final pass (Sedgewick [1]). Second, if a
          subfile is partitioned into two very unbalanced subfiles, the
          larger of them is flagged for special treatment: before it is
          partitioned, its end-points are swapped with two random points
          within it; this makes the worst case behaviour extremely
          unlikely.

          4. References

          [1]   Sedgewick R (1978) Implementing Quicksort Programs. Comm.
                ACM. 21 847--857.

          [2]   Singleton R C (1969) An Efficient Algorithm for Sorting with
                Minimal Storage: Algorithm 347. Comm. ACM. 12 185--187.
```

```
5. Parameters

 1:  RV(M2) -- DOUBLE PRECISION array                Input/Output
     On entry: elements M1 to M2 of RV must contain double
     precision values to be sorted. On exit: these values are
     rearranged into sorted order.

 2:  M1 -- INTEGER                                          Input
     On entry: the index of the first element of RV to be sorted.
     Constraint: M1 > 0.

 3:  M2 -- INTEGER                                          Input

     On entry: the index of the last element of RV to be sorted.
     Constraint: M2 >= M1.

 4:  ORDER -- CHARACTER*1                                   Input
     On entry: if ORDER is 'A', the values will be sorted into
     ascending (i.e., non-decreasing) order; if ORDER is 'D',
     into descending order. Constraint: ORDER = 'A' or 'D'.

 5:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry M2 < 1,

     or       M1 < 1,

     or       M1 > M2.

IFAIL= 2
     On entry ORDER is not 'A' or 'D'.

7. Accuracy

Not applicable.
```

```
         8. Further Comments

         The average time taken by the routine is approximately
         proportional to n*logn, where n = M2 - M1 + 1. The worst case
                                 2
         time is proportional to n  but this is extremely unlikely to
         occur.

         9. Example

         The example program reads a list of double precision numbers and
         sorts them into ascending order.

         The example program is not reproduced here. The source code for
         all example programs is distributed with the NAG Foundation
         Library software and should be available on-line.
\end{verbatim}

\end{page}
```

———-

16.5.48 Ranks a vector of double precision numbers

— nagm.ht —

```
\begin{page}{manpageXXm01daf}{NAG Documentation: m01daf}
\beginscroll
\begin{verbatim}

     M01DAF(3NAG)      Foundation Library (12/10/92)      M01DAF(3NAG)

         M01 -- Sorting                                          M01DAF
                 M01DAF -- NAG Foundation Library Routine Document

         Note: Before using this routine, please read the Users' Note for
         your implementation to check implementation-dependent details.
         The symbol (*) after a NAG routine name denotes a routine that is
         not included in the Foundation Library.

         1. Purpose

         M01DAF ranks a vector of double precision numbers in ascending or
```

```
descending order.

2. Specification

       SUBROUTINE M01DAF (RV, M1, M2, ORDER, IRANK, IFAIL)
       INTEGER          M1, M2, IRANK(M2), IFAIL
       DOUBLE PRECISION RV(M2)
       CHARACTER*1      ORDER

3. Description

M01DAF uses a variant of list-merging, as described by Knuth [1]
pp 165-166. The routine takes advantage of natural ordering in
the data, and uses a simple list insertion in a preparatory pass
to generate ordered lists of length at least 10. The ranking is
stable: equal elements preserve their ordering in the input data.

4. References

[1]   Knuth D E (1973) The Art of Computer Programming, Vol 3.
      Addison-Wesley.

5. Parameters

 1:  RV(M2) -- DOUBLE PRECISION array                        Input
     On entry: elements M1 to M2 of RV must contain double
     precision values to be ranked.

 2:  M1 -- INTEGER                                           Input
     On entry: the index of the first element of RV to be ranked.
     Constraint: M1 > 0.

 3:  M2 -- INTEGER                                           Input
     On entry: the index of the last element of RV to be ranked.
     Constraint: M2 >= M1.

 4:  ORDER -- CHARACTER*1                                    Input
     On entry: if ORDER is 'A', the values will be ranked in
     ascending (i.e., non-decreasing) order; if ORDER is 'D',
     into descending order. Constraint: ORDER = 'A' or 'D'.

 5:  IRANK(M2) -- INTEGER array                             Output
     On exit: elements M1 to M2 of IRANK contain the ranks of the
     corresponding elements of RV. Note that the ranks are in the
     range M1 to M2: thus, if RV(i) is the first element in the
     rank order, IRANK(i) is set to M1.

 6:  IFAIL -- INTEGER                                 Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
                   Introduction) the recommended value is 0.

                   On exit: IFAIL = 0 unless the routine detects an error (see
                   Section 6).

              6. Error Indicators and Warnings

              Errors detected by the routine:

              If on entry IFAIL = 0 or -1, explanatory error messages are
              output on the current error message unit (as defined by X04AAF).

              IFAIL= 1
                   On entry M2 < 1,

                   or       M1 < 1,

                   or       M1 > M2.

              IFAIL= 2
                   On entry ORDER is not 'A' or 'D'.

              7. Accuracy

              Not applicable.

              8. Further Comments

              The average time taken by the routine is approximately
              proportional to n*logn, where n = M2 - M1 + 1.

              9. Example

              The example program reads a list of double precision numbers and
              ranks them in ascending order.

              The example program is not reproduced here. The source code for
              all example programs is distributed with the NAG Foundation

16.5.49 Ranks the rows of a matrix of double precision numbers

— **nagm.ht** —

```
\begin{page}{manpageXXm01def}{NAG Documentation: m01def}
\beginscroll
\begin{verbatim}

     M01DEF(3NAG)      Foundation Library (12/10/92)      M01DEF(3NAG)

          M01 -- Sorting                                          M01DEF
                  M01DEF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          M01DEF ranks the rows of a matrix of double precision numbers in
          ascending or descending order.

          2. Specification

                 SUBROUTINE M01DEF (RM, LDM, M1, M2, N1, N2, ORDER, IRANK,
                1                   IFAIL)
                 INTEGER          LDM, M1, M2, N1, N2, IRANK(M2), IFAIL
                 DOUBLE PRECISION RM(LDM,N2)
                 CHARACTER*1      ORDER

          3. Description

          M01DEF ranks rows M1 to M2 of a matrix, using the data in columns
          N1 to N2 of those rows. The ordering is determined by first
          ranking the data in column N1, then ranking any tied rows
          according to the data in column N1 + 1, and so on up to column
          N2.

          M01DEF uses a variant of list-merging, as described by Knuth [1]
          pp 165-166. The routine takes advantage of natural ordering in
          the data, and uses a simple list insertion in a preparatory pass
          to generate ordered lists of length at least 10. The ranking is
          stable: equal rows preserve their ordering in the input data.
```

```

      Addison-Wesley.

5. Parameters

 1:  RM(LDM,N2) -- DOUBLE PRECISION array                   Input
     On entry: columns N1 to N2 of rows M1 to M2 of RM must
     contain double precision data to be ranked.

 2:  LDM -- INTEGER                                         Input
     On entry:
     the first dimension of the array RM as declared in the
     (sub)program from which M01DEF is called.
     Constraint: LDM >= M2.

 3:  M1 -- INTEGER                                          Input
     On entry: the index of the first row of RM to be ranked.
     Constraint: M1 > 0.

 4:  M2 -- INTEGER                                          Input
     On entry: the index of the last row of RM to be ranked.
     Constraint: M2 >= M1.

 5:  N1 -- INTEGER                                          Input
     On entry: the index of the first column of RM to be used.
     Constraint: N1 > 0.

 6:  N2 -- INTEGER                                          Input
     On entry: the index of the last column of RM to be used.
     Constraint: N2 >= N1.

 7:  ORDER -- CHARACTER*1                                   Input
     On entry: if ORDER is 'A', the rows will be ranked in
     ascending (i.e., non-decreasing) order; if ORDER is 'D',
     into descending order. Constraint: ORDER = 'A' or 'D'.

 8:  IRANK(M2) -- INTEGER array                            Output
     On exit: elements M1 to M2 of IRANK contain the ranks of the
     corresponding rows of RM. Note that the ranks are in the
     range M1 to M2: thus, if the ith row of RM is the first in
     the rank order, IRANK(i) is set to M1.

 9:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
                Section 6).

           6. Error Indicators and Warnings

           Errors detected by the routine:

           If on entry IFAIL = 0 or -1, explanatory error messages are
           output on the current error message unit (as defined by X04AAF).

           IFAIL= 1
                On entry M2 < 1,

                or       N2 < 1,

                or       M1 < 1,

                or       M1 > M2,

                or       N1 < 1,

                or       N1 > N2,

                or       LDM < M2.

           IFAIL= 2
                On entry ORDER is not 'A' or 'D'.

           7. Accuracy

           Not applicable.

           8. Further Comments

           The average time taken by the routine is approximately
           proportional to n*logn, where n = M2 - M1 + 1.

           9. Example

           The example program reads a matrix of double precision numbers
           and ranks the rows in ascending order.

           The example program is not reproduced here. The source code for
           all example programs is distributed with the NAG Foundation
           Library software and should be available on-line.

16.5.50 Ranks the columns of a matrix of double precision numbers

— **nagm.ht** —

```
\begin{page}{manpageXXm01djf}{NAG Documentation: m01djf}
\beginscroll
\begin{verbatim}

     M01DJF(3NAG)      Foundation Library (12/10/92)      M01DJF(3NAG)

          M01 -- Sorting                                           M01DJF
                  M01DJF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          M01DJF ranks the columns of a matrix of double precision numbers
          in ascending or descending order.

          2. Specification

                 SUBROUTINE M01DJF (RM, LDM, M1, M2, N1, N2, ORDER, IRANK,
                1                   IFAIL)
                 INTEGER          LDM, M1, M2, N1, N2, IRANK(N2), IFAIL
                 DOUBLE PRECISION RM(LDM,N2)
                 CHARACTER*1      ORDER

          3. Description

          M01DJF ranks columns N1 to N2 of a matrix, using the data in rows
          M1 to M2 of those columns. The ordering is determined by first
          ranking the data in row M1, then ranking any tied columns
          according to the data in row M1 + 1, and so on up to row M2.

          M01DJF uses a variant of list-merging, as described by Knuth [1]
          pp 165-166. The routine takes advantage of natural ordering in
          the data, and uses a simple list insertion in a preparatory pass
          to generate ordered lists of length at least 10. The ranking is
```

```
stable: equal columns preserve their ordering in the input data.

      Addison-Wesley.

5. Parameters

 1:  RM(LDM,N2) -- DOUBLE PRECISION array                  Input
     On entry: rows M1 to M2 of columns N1 to N2 of RM must
     contain double precision data to be ranked.

 2:  LDM -- INTEGER                                        Input
     On entry:
     the first dimension of the array RM as declared in the
     (sub)program from which M01DJF is called.
     Constraint: LDM >= M2.

 3:  M1 -- INTEGER                                         Input
     On entry: the index of the first row of RM to be used.
     Constraint: M1 > 0.

 4:  M2 -- INTEGER                                         Input
     On entry: the index of the last row of RM to be used.
     Constraint: M2 >= M1.

 5:  N1 -- INTEGER                                         Input
     On entry: the index of the first column of RM to be ranked.
     Constraint: N1 > 0.

 6:  N2 -- INTEGER                                         Input
     On entry: the index of the last column of RM to be ranked.
     Constraint: N2 >= N1.

 7:  ORDER -- CHARACTER*1                                  Input
     On entry: if ORDER is 'A', the columns will be ranked in
     ascending (i.e., non-decreasing) order; if ORDER is 'D',
     into descending order. Constraint: ORDER = 'A' or 'D'.

 8:  IRANK(N2) -- INTEGER array                           Output
     On exit: elements N1 to N2 of IRANK contain the ranks of the
     corresponding columns of RM. Note that the ranks are in the
     range N1 to N2: thus, if the ith column of RM is the first
     in the rank order, IRANK(i) is set to N1.

 9:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.
```

```
          On exit: IFAIL = 0 unless the routine detects an error (see
          Section 6).

     6. Error Indicators and Warnings

     Errors detected by the routine:

     If on entry IFAIL = 0 or -1, explanatory error messages are
     output on the current error message unit (as defined by X04AAF).

     IFAIL= 1
          On entry M2 < 1,

          or       N2 < 1,

          or       M1 < 1,

          or       M1 > M2,

          or       N1 < 1,

          or       N1 > N2,

          or       LDM < M2.

     IFAIL= 2
          On entry ORDER is not 'A' or 'D'.

     7. Accuracy

     Not applicable.

     8. Further Comments

     The average time taken by the routine is approximately
     proportional to n*logn, where n = N2 - N1 + 1.

     9. Example

     The example program reads a matrix of double precision numbers
     and ranks the columns in ascending order.

     The example program is not reproduced here. The source code for
     all example programs is distributed with the NAG Foundation
     Library software and should be available on-line.

16.5.51 Rearranges a vector of double precision numbers

— nagm.ht —

```
\begin{page}{manpageXXm01eaf}{NAG Documentation: m01eaf}
\beginscroll
\begin{verbatim}

     M01EAF(3NAG)      Foundation Library (12/10/92)      M01EAF(3NAG)

          M01 -- Sorting                                            M01EAF
                  M01EAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          M01EAF rearranges a vector of double precision numbers into the
          order specified by a vector of ranks.

          2. Specification

                 SUBROUTINE M01EAF (RV, M1, M2, IRANK, IFAIL)
                 INTEGER          M1, M2, IRANK(M2), IFAIL
                 DOUBLE PRECISION RV(M2)

          3. Description

          M01EAF is designed to be used typically in conjunction with the
          M01D- ranking routines. After one of the M01D- routines has been
          called to determine a vector of ranks, M01EAF can be called to
          rearrange a vector of real numbers into the rank order. If the
          vector of ranks has been generated in some other way, then
          M01ZBF(*) should be called to check its validity before M01EAF is
          called.

          4. References
```

```
None.

5. Parameters

 1:  RV(M2) -- DOUBLE PRECISION array               Input/Output
     On entry: elements M1 to M2 of RV must contain double
     precision values to be rearranged. On exit: these values are
     rearranged into rank order. For example, if IRANK(i) = M1,
     then the initial value of RV(i) is moved to RV(M1).

 2:  M1 -- INTEGER                                         Input

 3:  M2 -- INTEGER                                         Input
     On entry: M1 and M2 must specify the range of the ranks
     supplied in IRANK and the elements of RV to be rearranged.
     Constraint: 0 < M1 <= M2.

 4:  IRANK(M2) -- INTEGER array                            Input
     On entry: elements M1 to M2 of IRANK must contain a
     permutation of the integers M1 to M2, which are interpreted
     as a vector of ranks.

 5:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry M2 < 1,

     or       M1 < 1,

     or       M1 > M2.

IFAIL= 2
     Elements M1 to M2 of IRANK contain a value outside the range
     M1 to M2.

IFAIL= 3
```

```
               Elements M1 to M2 of IRANK contain a repeated value.

          If IFAIL = 2 or 3, elements M1 to M2 of IRANK do not contain a
          permutation of the integers M1 to M2. On exit, the contents of RV
          may be corrupted. To check the validity of IRANK without the risk
          of corrupting RV, use M01ZBF(*).

          7. Accuracy

          Not applicable.

          8. Further Comments

          The average time taken by the routine is approximately
          proportional to n, where n = M2 - M1 + 1.

          9. Example

          The example program reads a matrix of double precision numbers
          and rearranges its rows so that the elements of the kth column
          are in ascending order. To do this, the program first calls
          M01DAF to rank the elements of the kth column, and then calls
          M01EAF to rearrange each column into the order specified by the
          ranks. The value of k is read from the data-file.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

```

```
M01 -- Sorting                                          M01ZAF
        M01ZAF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

M01ZAF inverts a permutation, and hence converts a rank vector to an index vector, or vice versa.

2. Specification

```
       SUBROUTINE M01ZAF (IPERM, M1, M2, IFAIL)
       INTEGER          IPERM(M2), M1, M2, IFAIL
```

3. Description

There are two common ways of describing a permutation using an integer vector IPERM. The first uses ranks: IPERM(i) holds the position to which the ith data element should be moved in order to sort the data; in other words its rank in the sorted order. The second uses indices: IPERM(i) holds the current position of the data element which would occur in ith position in sorted order. For example, given the values

```
       3.5    5.9    2.9    0.5
```

to be sorted in ascending order, the ranks would be

```
       3      4      2      1
```

and the indices would be

```
       4      3      1      2
```

The M01D- routines generate ranks, and the M01E- routines require ranks to be supplied to specify the re-ordering. However if it is desired simply to refer to the data in sorted order without actually re-ordering them, indices are more convenient than ranks (see the example in Section 9).

M01ZAF can be used to convert ranks to indices, or indices to ranks, as the two permutations are inverses of one another.

4. References

```
None.

5. Parameters

 1:  IPERM(M2) -- INTEGER array                      Input/Output
     On entry: elements M1 to M2 of IPERM must contain a
     permutation of the integers M1 to M2. On exit: these
     elements contain the inverse permutation of the integers M1
     to M2.

 2:  M1 -- INTEGER                                          Input

 3:  M2 -- INTEGER                                          Input
     On entry: M1 and M2 must specify the range of elements used
     in the array IPERM and the range of values in the
     permutation, as specified under IPERM. Constraint: 0 < M1 <=
     M2.

 4:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry M2 < 1,

     or       M1 < 1,
     or       M1 > M2.
IFAIL= 2
     Elements M1 to M2 of IPERM contain a value outside the range
     M1 to M2.

IFAIL= 3
     Elements M1 to M2 of IPERM contain a repeated value.

If IFAIL = 2 or 3, elements M1 to M2 of IPERM do not contain a
permutation of the integers M1 to M2; on exit these elements are
usually corrupted. To check the validity of a permutation without
the risk of corrupting it, use M01ZBF(*).
```

```
          7. Accuracy

          Not applicable.

          8. Further Comments

          None.

          9. Example

          The example program reads a matrix of double precision numbers
          and prints its rows in ascending order as ranked by M01DEF. The
          program first calls M01DEF to rank the rows, and then calls
          M01ZAF to convert the rank vector to an index vector, which is
          used to refer to the rows in sorted order.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

16.6.1 Approximations of Special Functions

— **nags.ht** —

```
\begin{page}{manpageXXs}{NAG Documentation: s}
\beginscroll
\begin{verbatim}

     S(3NAG)          Foundation Library (12/10/92)          S(3NAG)

          S -- Approximations of Special Functions        Introduction -- S
                                   Chapter S
                      Approximations of Special Functions
```

1. Scope of the Chapter

This chapter is concerned with the provision of some commonly occurring physical and mathematical functions.

2. Background to the Problems

The majority of the routines in this chapter approximate real-valued functions of a single real argument, and the techniques involved are described in Section 2.1. In addition the chapter contains routines for elliptic integrals (see Section 2.2), Bessel and Airy functions of a complex argument (see Section 2.3) , and exponential of a complex argument.

2.1. Functions of a Single Real Argument

Most of the routines for functions of a single real argument have been based on truncated Chebyshev expansions. This method of approximation was adopted as a compromise between the conflicting requirements of efficiency and ease of implementation on many different machine ranges. For details of the reasons behind this choice and the production and testing procedures followed in constructing this chapter see Schonfelder [7].

Basically if the function to be approximated is $f(x)$, then for xis in $[a,b]$ an approximation of the form

$$f(x)=g(x) \sum_{r=0}' C_r T_r(t)$$

is used, ($\sum'$ denotes, according to the usual convention, a summation in which the first term is halved), where $g(x)$ is some suitable auxiliary function which extracts any singularities, asymptotes and, if possible, zeros of the function in the range in question and $t=t(x)$ is a mapping of the general range $[a,b]$ to the specific range $[-1,+1]$ required by the Chebyshev polynomials, $T_r(t)$. For a detailed description of the properties of the Chebyshev polynomials see Clenshaw [5] and Fox and Parker [6].

The essential property of these polynomials for the purposes of function approximation is that $T_n(t)$ oscillates between ± 1 and it takes its extreme values $n+1$ times in the interval $[-1,+1]$. Therefore, provided the coefficients C decrease in magnitude

$_r$
sufficiently rapidly the error made by truncating the Chebyshev expansion after n terms is approximately given by

$$E(t) \simeq C_n T_n(t)$$

That is the error oscillates between $\pm C_n$ and takes its extreme value n+1 times in the interval in question. Now this is just the condition that the approximation be a mini-max representation, one which minimizes the maximum error. By suitable choice of the interval, [a,b], the auxiliary function, g(x), and the mapping of the independent variable, t(x), it is almost always possible to obtain a Chebyshev expansion with rapid convergence and hence truncations that provide near mini-max polynomial approximations to the required function. The difference between the true mini-max polynomial and the truncated Chebyshev expansion is seldom sufficiently great to be of significance.

The evaluation of the Chebyshev expansions follows one of two methods. The first and most efficient, and hence most commonly used, works with the equivalent simple polynomial. The second method, which is used on the few occasions when the first method proves to be unstable, is based directly on the truncated Chebyshev series and uses backward recursion to evaluate the sum. For the first method, a suitably truncated Chebyshev expansion (truncation is chosen so that the error is less than the machine precision) is converted to the equivalent simple polynomial. That is we evaluate the set of coefficients b_r such that

$$y(t) = \sum_{r=0}^{n-1} b_r t^r = {\sum_{r=0}^{n-1}}' C_r T_r(t).$$

The polynomial can then be evaluated by the efficient Horner's method of nested multiplications,

$$y(t) = (b_0 + t(b_1 + t(b_2 + \ldots t(b_{n-2} + t b_{n-1}))) \ldots).$$

This method of evaluation results in efficient routines but for some expansions there is considerable loss of accuracy due to cancellation effects. In these cases the second method is used. It is well known that if

$$b_{n-1}=C_{n-1}$$

$$b_{n-2}=2tb_{n-1}+C_{n-2}$$

$$b_j=2tb_{j+1}-b_{j+2}+C_j\ ,\quad j=n-3,n-4,...,0$$

then

$$\sum_{r=0}{}' C_r T_r(t)=\frac{1}{2}(b_0-b_2)$$

and this is always stable. This method is most efficiently implemented by using three variables cyclically and explicitly constructing the recursion.

That is,

$$
\begin{aligned}
&(\alpha) = C_{n-1}\\
&(\beta) = 2t(\alpha)+C_{n-2}\\
&(\gamma) = 2t(\beta)-(\alpha)+C_{n-3}\\
&(\alpha) = 2t(\gamma)-(\beta)+C_{n-4}\\
&(\beta) = 2t(\alpha)-(\gamma)+C_{n-5}\\
&\quad ...\\
&\quad ...\\

\end{aligned}
$$

The auxiliary functions used are normally functions compounded of simple polynomial (usually linear) factors extracting zeros, and the primary compiler-provided functions, sin, cos, ln, exp, sqrt, which extract singularities and/or asymptotes or in some cases basic oscillatory behaviour, leaving a smooth well-behaved function to be approximated by the Chebyshev expansion which can therefore be rapidly convergent.

The mappings of [a,b] to [-1,+1] used, range from simple linear mappings to the case when b is infinite and considerable improvement in convergence can be obtained by use of a bilinear form of mapping. Another common form of mapping is used when the function is even, that is it involves only even powers in its expansion. In this case an approximation over the whole interval [-a,a] can be provided using a mapping $t=2\left(\frac{x}{a}\right)^2-1$. This embodies the evenness property but the expansion in t involves all powers and hence removes the necessity of working with an expansion with half its coefficients zero.

For many of the routines an analysis of the error in principle is given, viz, if E and (nabla) are the absolute errors in function and argument and (epsilon) and (delta) are the corresponding relative errors, then

$$E\tilde{=}|f'(x)|(nabla)$$

$$E\tilde{=}|xf'(x)|(delta)$$

$$(epsilon)\tilde{=}\left|\frac{xf'(x)}{f(x)}\right|(delta)$$

If we ignore errors that arise in the argument of the function by propagation of data errors etc and consider only those errors that result from the fact that a real number is being represented in the computer in floating-point form with finite precision, then (delta) is bounded and this bound is independent of the magnitude of x; e.g. on an 11-digit machine

$$|(delta)|<=10^{-11}.$$

(This of course implies that the absolute error (nabla)=x(delta) is also bounded but the bound is now dependent on x). However because of this the last two relations above are probably of more interest. If possible the relative error propagation is discussed; that is the behaviour of the error amplification factor |xf'(x)/f(x)| is described, but in some cases, such as near zeros of the function which cannot be extracted explicitly, absolute error in the result is the quantity of significance and here the factor |xf'(x)| is described. In general, testing of the functions has shown that their error behaviour follows fairly well these theoretical error behaviours. In regions, where the error amplification factors are less than or of the order of one, the errors are slightly larger than the above predictions. The errors are here limited largely by the finite precision of arithmetic in the machine but (epsilon) is normally no more than a few times greater than the bound on (delta). In regions where the amplification factors are large, order of ten or greater, the theoretical analysis gives a good measure of the accuracy obtainable.

It should be noted that the definitions and notations used for the functions in this chapter are all taken from Abramowitz and Stegun [1]. Users are strongly recommended to consult this book for details before using the routines in this chapter.

2.2. Approximations to Elliptic Integrals

The functions provided here are symmetrised variants of the classic elliptic integrals. These alternative definitions have been suggested by Carlson (see [2], [3] and [4]) and he also developed the basic algorithms used in this chapter.

The standard integral of the first kind is represented by

$$R_F(x,y,z)=\frac{1}{2}\int_0^{\infty}\frac{dt}{\sqrt{(t+x)(t+y)(t+z)}}$$

where x,y,z>=0 and at most one may be equal to zero.

The normalisation factor, $\frac{1}{2}$, is chosen so as to make

$$R_F(x,x,x)=1/\sqrt{x}.$$

If any two of the variables are equal, R_F degenerates into the second function

$$R_C(x,y)=R_F(x,y,y)=\frac{1}{2}\int_0^{\infty}\frac{dt}{\sqrt{t+x}(t+y)}$$

where the argument restrictions are now x>=0 and y/=0.

This function is related to the logarithm or inverse hyperbolic functions if 0<y<x, and to the inverse circular functions if 0<=x<=y.

The integrals of the second kind are defined by

$$R_D(x,y,z)=\frac{3}{2}\int_0^{\infty}\frac{dt}{\sqrt{(t+x)(t+y)(t+z)^3}}$$

with z>0, x>=0 and y>=0 but only one of x or y may be zero.

The function is a degenerate special case of the integral of the third kind

$$R_J(x,y,z,\rho)=\frac{3}{2}\int_0^{\infty}\frac{dt}{\left(\sqrt{(t+x)(t+y)(t+z)}\right)(t+\rho)}$$

with $\rho\neq 0$, x,y,z>=0 with at most one equality holding. Thus $R_D(x,y,z)=R_J(x,y,z,z)$. The normalisation of both these functions is chosen so that

$$R_D(x,x,x)=R_J(x,x,x,x)=1/(x\sqrt{x})$$

The algorithms used for all these functions are based on duplication theorems. These allow a recursion system to be established which constructs a new set of arguments from the old using a combination of arithmetic and geometric means. The value of the function at the original arguments can then be simply related to the value at the new arguments. These recursive reductions are used until the arguments differ from the mean by an amount small enough for a Taylor series about the mean to give sufficient accuracy when retaining terms of order less than six. Each step of the recurrences reduces the difference from the mean by a factor of four, and as the truncation error is of order six, the truncation error goes like $(4096)^{-n}$, where n is the number of iterations.

```
The above forms can be related to the more traditional canonical
forms (see Abramowitz and Stegun [1], 17.2).

                 2               2                2
If we write q=cos (phi),r=1-m.sin (phi),s=1+n.sin (phi), where
          1
0<(phi)<= -(pi), we have: the elliptic integral of the first
          2
kind:

              sin(phi)      -1/2      1-/2
              /          2         2
  F((phi)|m)= |       (1-t )   (1-mt )   dt=sin(phi).R (q,r,1);
              /                                     F
              0

the elliptic integral of the second kind:

                       sin(phi)      -1/2      -1/2
                       /          2         2
         E((phi)|m) =  |       (1-t )   (1-mt )  dt
                       /
                       0
                                          1     3
                    = sin(phi).R (q,r,1)- -m.sin (phi).R (q,r,1)
                               F          3             D

the elliptic integral of the third kind:

                       sin(phi)      -1/2      -1/2
                       /          2         2         2 -1
    (Pi)(n;(phi)|m) =  |       (1-t )   (1-mt )   (1+nt )  dt
                       /
                       0
                                          1     3
                    =sin(phi).R (q,r,1)- -n.sin (phi).R (q,r,1,s)
                              F          3             J

Also the complete elliptic integral of the first kind:

            (pi)/2
            /            2       -1/2
      K(m)= |     (1-m.sin (theta))   d(theta)=R (0,1-m,1);
            /                                   F
            0

the complete elliptic integral of the second kind:

      (pi)/2
```

$$E(m)=\int_0 (1-m.\sin^2(\theta))^{1/2}\,d(\theta)=R_F(0,1-m,1)-\frac{1}{3}mR_D(0,1-m,1).$$

2.3. Bessel and Airy Functions of a Complex Argument

The routines for Bessel and Airy functions of a real argument are based on Chebyshev expansions, as described in Section 2.1. The routines for functions of a complex argument, however, use different methods. These routines relate all functions to the modified Bessel functions $I_{(\nu)}(z)$ and $K_{(\nu)}(z)$ computed in the right-half complex plane, including their analytic continuations. $I_{(\nu)}$ and $K_{(\nu)}$ are computed by different methods according to the values of $z$and (ν). The methods include power series, asymptotic expansions and Wronskian evaluations. The relations between functions are based on well known formulae (see Abramowitz and Stegun [1]).

3. Recommendations on Choice and Use of Routines

3.1. Elliptic Integrals

IMPORTANT ADVICE: users who encounter elliptic integrals in the course of their work are strongly recommended to look at transforming their analysis directly to one of the Carlson forms, rather than the traditional canonical Legendre forms. In general, the extra symmetry of the Carlson forms is likely to simplify the analysis, and these symmetric forms are much more stable to calculate.

The routine S21BAF for R_C is largely included as an auxiliary to the other routines for elliptic integrals. This integral essentially calculates elementary functions, e.g.

$$\ln x=(x-1).R_C\left(\left(\frac{1+x}{2}\right)^2,x\right),x>0;$$

$$\arcsin x=x.R_C(1-x^2,1),|x|<=1;$$

$$\operatorname{arcsinh} x=x.R_C(1+x^2,1),\ \text{etc}$$

In general this method of calculating these elementary functions is not recommended as there are usually much more efficient specific routines available in the Library. However, S21BAF may be used, for example, to compute lnx/(x-1) when x is close to 1, without the loss of significant figures that occurs when lnx and x-1 are computed separately.

3.2. Bessel and Airy Functions

For computing the Bessel functions $J_{(nu)}(x)$, $Y_{(nu)}(x)$, $I_{(nu)}(x)$ and $K_{(nu)}(x)$ where x is real and (nu)=0 or 1, special routines are provided, which are much faster than the more general routines that allow a complex argument and arbitrary real (nu)>=0 functions and their derivatives Ai(x), Bi(x), Ai'(x), Bi'(x) for a real argument which are much faster than the routines for complex arguments.

     S01EAF(3NAG)      Foundation Library (12/10/92)      S01EAF(3NAG)

          S01 -- Approximations of Special Functions                 S01EAF
                  S01EAF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S01EAF evaluates the exponential function e^z, for complex z.

2. Specification

```
       COMPLEX(KIND(1.0D0)) FUNCTION S01EAF (Z, IFAIL)
       INTEGER                               IFAIL
       COMPLEX(KIND(1.0D0))                  Z
```

3. Description

This routine evaluates the exponential function e^z, taking care to avoid machine overflow, and giving a warning if the result cannot be computed to more than half precision. The function is evaluated as $e^z=e^x(cosy+isiny)$, where x and y are the real and imaginary parts respectively of z.

Since cosy and siny are less than or equal to 1 in magnitude, it is possible that e^x may overflow although $e^x cosy$ or $e^x siny$ does not. In this case the alternative formula $sign(cosy)e^{x+ln|cosy|}$ is used for the real part of the result, and $sign(siny)e^{x+ln|siny|}$ for the imaginary part. If either part of the result still overflows, a warning is returned through parameter IFAIL.

If Im z is too large, precision may be lost in the evaluation of siny and cosy. Again, a warning is returned through IFAIL.

4. References

None.

5. Parameters

```
 1:  Z -- COMPLEX(KIND(1.0D0))                                  Input
     On entry: the argument z of the function.
 2:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     The real part of the result overflows, and is set to the
     largest safe number with the correct sign. The imaginary
     part of the result is meaningful.

IFAIL= 2
     The imaginary part of the result overflows, and is set to
     the largest safe number with the correct sign. The real part
     of the result is meaningful.

IFAIL= 3
     Both real and imaginary parts of the result overflow, and
     are set to the largest safe number with the correct signs.

IFAIL= 4
     The computed result is accurate to less than half precision,
     due to the size of Im z.

IFAIL= 5
     The computed result has no precision, due to the size of Im
     z, and is set to zero.

7. Accuracy

Accuracy is limited in general only by the accuracy of the
Fortran intrinsic functions in the computation of siny, cosy and
 x
e , where x=Re z, y=Im z. As y gets larger, precision will
probably be lost due to argument reduction in the evaluation of
the sine and cosine functions, until the warning error IFAIL = 4

occurs when y gets larger than \/1/(epsilon), where (epsilon) is
the machine precision. Note that on some machines, the intrinsic
functions SIN and COS will not operate on arguments larger than

about \/1/(epsilon), and so IFAIL can never return as 4.
```

```
          In the comparatively rare event that the result is computed by
                                x+ln|cosy|                x+ln|siny|
          the formulae sign(cosy)e           and sign(siny)e          , a
          further small loss of accuracy may be expected due to rounding
          errors in the logarithmic function.

          8. Further Comments

          None.

          9. Example

          The example program reads values of the argument z from a file,
          evaluates the function at each value of z and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.
```

1. Purpose

S13AAF returns the value of the exponential integral $E_1(x)$, via the routine name.

2. Specification

```
       DOUBLE PRECISION FUNCTION S13AAF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X
```

3. Description

The routine calculates an approximate value for

$$E_1(x)=\int_x^{\infty} \frac{e^{-u}}{u}\,du \text{ , } x>0.$$

For 0<x<=4, the approximation is based on the Chebyshev expansion

$$E_1(x)=y(t)-\ln x=\sum_r{}' a_r T_r(t)-\ln x \text{ , where } t=\frac{1}{2}x-1.$$

For x>4,

$$E_1(x)=\frac{e^{-x}}{x}y(t)=\frac{e^{-x}}{x}\sum_r{}' a_r T_r(t),$$

$$\text{where } t=-1.0+14.5/(x+3.25)=\frac{11.25-x}{3.25+x}.$$

In both cases, -1<=t<=+1.

To guard against producing underflows, if $x>x_{hi}$ the result is set directly to zero. For the value x_{hi} see the Users' Note for your implementation.

4. References

[1] Abramowitz M and Stegun I A (1965) Handbook of Mathematical Functions. Dover Publications. Ch. 26.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function. Constraint: X > 0. 0.

2: IFAIL -- INTEGER Input/Output
Before entry, IFAIL must be assigned a value. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

Unless the routine detects an error (see Section 6), IFAIL contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
The routine has been called with an argument less than or equal to zero for which the function is not defined. The result returned is zero.

7. Accuracy

If (delta) and (epsilon) are the relative errors in argument and result respectively, then in principle,

$$|(\text{epsilon})| \tilde{=} \left| \frac{e^{-x}}{E_1(x)} * (\text{delta}) \right|$$

so the relative error in the argument is amplified in the result by at least a factor $e^{-x}/E_1(x)$. The equality should hold if (delta) is greater than the machine precision ((delta) due to data errors etc) but if (delta) is simply a result of round-off in the machine representation, it is possible that an extra figure may be lost in internal calculation and round-off.

The behaviour of this amplification factor is shown in Figure 1.

```
                                 Figure 1
                  Please see figure in printed Reference Manual

          It should be noted that, for small x, the amplification factor
          tends to zero and eventually the error in the result will be
          limited by machine precision.

          For large x,

                             (epsilon)~x(delta)=(Delta),

          the absolute error in the argument.

          8. Further Comments

          None.

          9. Example

          The example program reads values of the argument x from a file,
          evaluates the function at each value of x and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

```

S13ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S13ACF returns the value of the cosine integral

$$Ci(x)=\gamma+\ln x+\int_0^x \frac{\cos u-1}{u}du, \quad x>0$$

via the routine name, where γ denotes Euler's constant.

2. Specification

```
       DOUBLE PRECISION FUNCTION S13ACF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X
```

3. Description

The routine calculates an approximate value for Ci(x).

For $0<x\le16$ it is based on the Chebyshev expansion

$$Ci(x)=\ln x+{\sum_{r=0}}' a_r T_r(t) , \quad t=2\left(\frac{x}{16}\right)^2-1.$$

For $16<x<x_{hi}$ where the value of x_{hi} is given in the Users' Note for your implementation,

$$Ci(x)=\frac{f(x)\sin x}{x} \frac{g(x)\cos x}{x^2}$$

where $f(x)={\sum_{r=0}}' f_r T_r(t)$ and $g(x)={\sum_{r=0}}' g_r T_r(t)$, $t=2\left(\frac{16}{x}\right)^2-1.$

For $x>=x_{hi}$, Ci(x)=0 to within the accuracy possible (see Section 7).

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function. Constraint: X > 0. 0.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
The routine has been called with an argument less than or equal to zero for which the function is not defined. The result returned is zero.

7. Accuracy

If E and (epsilon) are the absolute and relative errors in the result and (delta) is the relative error in the argument then in principle these are related by

$$|E|\tilde{=}|(delta)cosx| \text{ and } |(epsilon)|\tilde{=}\left|\frac{(delta)cosx}{Ci(x)}\right|.$$

That is accuracy will be limited by machine precision near the origin and near the zeros of cosx, but near the zeros of Ci(x) only absolute accuracy can be maintained.

The behaviour of this amplification is shown in Figure 1.

Figure 1

```
                Please see figure in printed Reference Manual

                                           sinx
          For large values of x, Ci(x)~ ---- therefore
                                            x
          (epsilon)~(delta)xcotx and since (delta) is limited by the finite
          precision of the machine it becomes impossible to return results
          which have any relative accuracy. That is, when x>=1/(delta) we
          have that |Ci(x)|<=1/x~E and hence is not significantly different
          from zero.

          Hence x   is chosen such that for values of x>=x  , Ci(x) in
                 hi                                      hi
          principle would have values less than the machine precision and
          so is essentially zero.

          8. Further Comments

          For details of the time taken by the routine see the Users' Note
          for your implementation.

          9. Example

          The example program reads values of the argument x from a file,
          evaluates the function at each value of x and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

S13 -- Approximations of Special Functions S13ADF

S13ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S13ADF returns the value of the sine integral

$$Si(x)= \int_0^x \frac{\sin u}{u} du,$$

via the routine name.

2. Specification

```
       DOUBLE PRECISION FUNCTION S13ADF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X
```

3. Description

The routine calculates an approximate value for Si(x).

For $|x|<=16.0$ it is based on the Chebyshev expansion

$$Si(x)=x \sum_{r=0}{}' a_r T_r(t) , t=2\left(\frac{x}{16}\right)^2 -1.$$

For $16<|x|<x_{hi}$, where x_{hi} is an implementation dependent number,

$$Si(x)=sign(x)\left\{ \frac{\pi}{2} \frac{f(x)\cos x}{x} \frac{g(x)\sin x}{x^2} \right\}$$

where $f(x)= \sum{}' f T (t)$ and $g(x)= \sum{}' g T (t)$, $t=2\left(\frac{16}{x}\right)^2 -1$.

```
            --   r r              --   r r        ( x )
            r=0                   r=0
```

For $|x|>=x_{hi}$, $Si(x)= \frac{1}{2}(pi)signx$ to within machine precision.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL has been included for consistency with other routines in this chapter.

7. Accuracy

If (delta) and (epsilon) are the relative errors in the argument and result, respectively, then in principle

$$|(epsilon)|\simeq\left|\frac{(delta)sinx}{Si(x)}\right|.$$

The equality may hold if (delta) is greater than the machine precision ((delta) due to data errors etc) but if (delta) is simply due to round-off in the machine representation, then since the factor relating (delta) to (epsilon) is always less than one, the accuracy will be limited by machine precision.

8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

```
         9. Example

         The example program reads values of the argument x from a file,
         evaluates the function at each value of x and prints the results.

         The example program is not reproduced here. The source code for
         all example programs is distributed with the NAG Foundation
         Library software and should be available on-line.

16.6.6 Returns the value of the Gamma function

— nags.ht —

```
\begin{page}{manpageXXs14aaf}{NAG Documentation: s14aaf}
\beginscroll
\begin{verbatim}

     S14AAF(3NAG)      Foundation Library (12/10/92)      S14AAF(3NAG)

         S14 -- Approximations of Special Functions                S14AAF
                 S14AAF -- NAG Foundation Library Routine Document

         Note: Before using this routine, please read the Users' Note for
         your implementation to check implementation-dependent details.
         The symbol (*) after a NAG routine name denotes a routine that is
         not included in the Foundation Library.

         1. Purpose

         S14AAF returns the value of the Gamma function (Gamma)(x), via
         the routine name.

         2. Specification

                DOUBLE PRECISION FUNCTION S14AAF (X, IFAIL)
                INTEGER          IFAIL
```

```
       DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Gamma function (Gamma)(x). The routine is based on the Chebyshev expansion:

```
                    --'
       (Gamma)(1+u)= >   a T (t) , where 0<=u<1 , t=2u-1,
                    --    r r
                    r=0
```

and uses the property (Gamma)(1+x)=x(Gamma)(x). If x=N+1+u where N is integral and 0<=u<1 then it follows that:

```
     for N>0  (Gamma)(x)=(x-1)(x-2)...(x-N)(Gamma)(1+u),

     for N=0  (Gamma)(x)=(Gamma)(1+u),

                                  (Gamma)(1+u)
     for N<0  (Gamma)(x)= ---------------------.
                              x(x+1)(x+2)...(x-N-1)
```

There are four possible failures for this routine:

(i) if x is too large, there is a danger of overflow since (Gamma)(x) could become too large to be represented in the machine;

(ii) if x is too large and negative, there is a danger of underflow;

(iii) if x is equal to a negative integer, (Gamma)(x) would overflow since it has poles at such points;

(iv) if x is too near zero, there is again the danger of

```
                                                    1
overflow on some machines. For small x, (Gamma)(x)~= -, and
                                                    x
```

on some machines there exists a range of non-zero but small values of x for which 1/x is larger than the greatest representable value.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

```
 1:  X -- DOUBLE PRECISION                                  Input
     On entry: the argument x of the function. Constraint: X must
     not be a negative integer.

 2:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     The argument is too large. On soft failure the routine
     returns the approximate value of (Gamma)(x) at the nearest
     valid argument.

IFAIL= 2
     The argument is too large and negative. On soft failure the
     routine returns zero.

IFAIL= 3
     The argument is too close to zero. On soft failure the
     routine returns the approximate value of (Gamma)(x) at the
     nearest valid argument.

IFAIL= 4
     The argument is a negative integer, at which value
     (Gamma)(x) is infinite. On soft failure the routine returns
     a large positive value.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument
and the result respectively. If (delta) is somewhat larger than
the machine precision (i.e., is due to data errors etc), then
(epsilon) and (delta) are approximately related by:

                  (epsilon)~=|x(Psi)(x)|(delta)

(provided (epsilon) is also greater than the representation
                                                (Gamma)'(x)
error). Here (Psi)(x) is the digamma function  -----------.
                                                (Gamma)(x)
Figure 1 shows the behaviour of the error amplification factor
|x(Psi)(x)|.
```

```
                                   Figure 1
                  Please see figure in printed Reference Manual

          If (delta) is of the same order as machine precision, then
          rounding errors could make (epsilon) slightly larger than the
          above relation predicts.

          There is clearly a severe, but unavoidable, loss of accuracy for
          arguments close to the poles of (Gamma)(x) at negative integers.
          However relative accuracy is preserved near the pole at x=0 right
          up to the point of failure arising from the danger of overflow.

          Also accuracy will necessarily be lost as x becomes large since
          in this region

                               (epsilon)~=(delta)xlnx.

          However since (Gamma)(x) increases rapidly with x, the routine
          must fail due to the danger of overflow before this loss of
          accuracy is too great. (e.g. for x=20, the amplification factor
          ~= 60.)

          8. Further Comments

          For details of the time taken by the routine see the Users' Note
          for your implementation.

          9. Example

          The example program reads values of the argument x from a file,
          evaluates the function at each value of x and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

16.6.7 Returns a value for the logarithm of the Gamma function

— nags.ht —

```
\begin{page}{manpageXXs14abf}{NAG Documentation: s14abf}
\beginscroll
\begin{verbatim}

     S14ABF(3NAG)      Foundation Library (12/10/92)      S14ABF(3NAG)

          S14 -- Approximations of Special Functions                S14ABF
                  S14ABF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          S14ABF returns a value for the logarithm of the Gamma function,
          ln(Gamma)(x), via the routine name.

          2. Specification

                 DOUBLE PRECISION FUNCTION S14ABF (X, IFAIL)
                 INTEGER          IFAIL
                 DOUBLE PRECISION X

          3. Description

          This routine evaluates an approximation to ln(Gamma)(x). It is
          based on two Chebyshev expansions.

          For 0<x<=x     , ln(Gamma)(x)=-lnx to within machine accuracy.
                    small

          For x     <x<=15.0, the recursive relation
               small
          (Gamma)(1+x)=x(Gamma)(x) is used to reduce the calculation to one
          involving (Gamma)(1+u), 0<=u<1 which is evaluated as:

                                       --'
                         (Gamma)(1+u)= >   a T (t),  t=2u-1.
                                       --   r r
                                       r=0

          Once (Gamma)(x) has been calculated, the required result is
          produced by taking the logarithm.
```

For $15.0<x\le x_{big}$,

$$\ln\Gamma(x)=(x-\frac{1}{2})\ln x-x+\frac{1}{2}\ln 2\pi+y(x)/x$$

where $y(x)=\sum_{r=0}{}' b_r T_r(t)$, $t=2\left(\frac{15}{x}\right)^2-1$.

For $x_{big}<x\le x_{vbig}$ the term $y(x)/x$ is negligible and so its calculation is omitted.

For $x>x_{vbig}$ there is a danger of setting overflow so the routine must fail.

For $x\le 0.0$ the function is not defined and the routine fails.

Note: x_{small} is calculated so that if $x<x_{small}$, $\Gamma(x)=1/x$ to within machine accuracy. x_{big} is calculated so that if $x>x_{big}$,

$$\ln\Gamma(x)=(x-\frac{1}{2})\ln x-x+\frac{1}{2}\ln 2\pi$$

to within machine accuracy. x_{vbig} is calculated so that $\ln\Gamma(x_{vbig})$ is close to the value returned by X02ALF(*).

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function. Constraint: X > 0. 0.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential

Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
X <= 0.0, the function is undefined. On soft failure, the routine returns zero.

IFAIL= 2
X is too large, the function would overflow. On soft failure, the routine returns the value of the function at the largest permissible argument.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively, and E be the absolute error in the result.

If (delta) is somewhat larger than the relative machine precision, then

```
                                         |  x*(Psi)(x) |
  E~=|x*(Psi)(x)|(delta) and (epsilon)~=| ------------|(delta)
                                         | ln(Gamma)(x)|

                                         (Gamma)'(x)
where (Psi)(x) is the digamma function  -----------. Figure 1 and
                                         (Gamma)(x)
Figure 2 show the behaviour of these error amplification factors.
```

Figure 1
Please see figure in printed Reference Manual

Figure 2
Please see figure in printed Reference Manual

These show that relative error can be controlled, since except near x=1 or 2 relative error is attenuated by the function or at least is not greatly amplified.

```
                        (    1 )
For large x, (epsilon)~=(1+ ---)(delta) and for small x,
                        (   lnx)
```

```
                  1
(epsilon)~= ---(delta).
            lnx

The function ln(Gamma)(x) has zeros at x=1 and 2 and hence
relative accuracy is not maintainable near those points. However
absolute accuracy can still be provided near those zeros as is
shown above.

If however, (delta) is of the order of the machine precision,
then rounding errors in the routine's internal arithmetic may
result in errors which are slightly larger than those predicted
by the equalities. It should be noted that even in areas where
strong attenuation of errors is predicted the relative precision
is bounded by the effective machine precision.

8. Further Comments

For details of the time taken by the routine see the Users' Note
for your implementation.

9. Example

The example program reads values of the argument x from a file,
evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

16.6.8 Incomplete gamma functions P(a,x) and Q(a,x)

— **nags.ht** —

```
\begin{page}{manpageXXs14baf}{NAG Documentation: s14baf}
\beginscroll
\begin{verbatim}

     S14BAF(3NAG)      Foundation Library (12/10/92)      S14BAF(3NAG)
```

S14 -- Approximations of Special Functions S14BAF

S14BAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S14BAF computes values for the incomplete gamma functions P(a,x) and Q(a,x).

2. Specification

```
      SUBROUTINE S14BAF (A, X, TOL, P, Q, IFAIL)
      INTEGER          IFAIL
      DOUBLE PRECISION A, X, TOL, P, Q
```

3. Description

This subroutine evaluates the incomplete gamma functions in the normalised form

$$P(a,x)=\frac{1}{\Gamma(a)}\int_0^x t^{a-1}e^{-t}\,dt,$$

$$Q(a,x)=\frac{1}{\Gamma(a)}\int_x^{\infty} t^{a-1}e^{-t}\,dt,$$

with x>=0 and a>0, to a user-specified accuracy. With this normalisation, P(a,x)+Q(a,x)=1.

Several methods are used to evaluate the functions depending on the arguments a and x, the methods including Taylor expansion for P(a,x), Legendre's continued fraction for Q(a,x), and power series for Q(a,x). When both a and x are large, and a~=x, the uniform asymptotic expansion of Temme [3] is employed for greater efficiency - specifically, this expansion is used when a>=20 and 0.7a<=x<=1.4a.

```
Once either of P or Q is computed, the other is obtained by
subtraction from 1. In order to avoid loss of relative precision
in this subtraction, the smaller of P and Q is computed first.

This routine is derived from subroutine GAM in Gautschi [2].

      Functions for Large Values of the Parameters. Algorithms for
      Approximation. (ed J C Mason and M G Cox) Oxford University
      Press.

5. Parameters

 1:  A -- DOUBLE PRECISION                                  Input
     On entry: the argument a of the functions. Constraint: A >
     0.0.

 2:  X -- DOUBLE PRECISION                                  Input
     On entry: the argument x of the functions. Constraint: X >=
     0.0.

 3:  TOL -- DOUBLE PRECISION                                Input
     On entry: the relative accuracy required by the user in the
     results. If S14BAF is entered with TOL greater than 1.0 or
     less than machine precision, then the value of machine
     precision is used instead.

 4:  P -- DOUBLE PRECISION                                 Output

 5:  Q -- DOUBLE PRECISION                                 Output
     On exit: the values of the functions P(a,x) and Q(a,x)
     respectively.

 6:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings
```

```
          Errors detected by the routine:

          IFAIL= 1
               On entry A <= 0.0.

          IFAIL= 2
               On entry X < 0.0.

          IFAIL= 3
               Convergence of the Taylor series or Legendre continued
               fraction fails within 600 iterations. This error is
               extremely unlikely to occur; if it does, contact NAG.

          7. Accuracy

          There are rare occasions when the relative accuracy attained is
          somewhat less than that specified by parameter TOL. However, the
          error should never exceed more than one or two decimal places.
          Note also that there is a limit of 18 decimal places on the
          achievable accuracy, because constants in the routine are given
          to this precision.

          8. Further Comments

          The time taken for a call of S14BAF depends on the precision
          requested through TOL, and also varies slightly with the input
          arguments a and x.

          9. Example

          The example program reads values of the argument a and x from a
          file, evaluates the function and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

16.6.9 Returns the value of the complementary error function

— nags.ht —

```
\begin{page}{manpageXXs15adf}{NAG Documentation: s15adf}
\beginscroll
\begin{verbatim}

     S15ADF(3NAG)      Foundation Library (12/10/92)      S15ADF(3NAG)

          S15 -- Approximations of Special Functions                S15ADF
                  S15ADF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          S15ADF returns the value of the complementary error function,
          erfcx, via the routine name.

          2. Specification

                 DOUBLE PRECISION FUNCTION S15ADF (X, IFAIL)
                 INTEGER          IFAIL
                 DOUBLE PRECISION X

          3. Description

          The routine calculates an approximate value for the complement of
          the error function

                                                 2
                                          infty -u
                                     2    /
                          erfc x= ------ |    e   du=1-erf x.
                                          /
                                  \/(pi) x

          For x>=0, it is based on the Chebyshev expansion

                                             2
                                           -x
                                   erfc x=e   y(x),

                      --'
          where y(x)= >   a T (t) and t=(x-3.75)/(x+3.75), -1<=t<=+1.
                      --   r r
```

r=0

For $x>=x_{hi}$, where there is a danger of setting underflow, the result is returned as zero.

For x<0, erfc $x=2-e^{-x^2}y(|x|)$.

For $x<x_{low}<0$, the result is returned as 2.0 which is correct to within machine precision. The values of x_{hi} and x_{low} are given in the Users' Note for your implementation.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL has been included for consistency with other routines in this chapter.

7. Accuracy

If (delta) and (epsilon) are relative errors in the argument and result, respectively, then in principle

$$|(epsilon)|\tilde{=}\left|\frac{2xe^{-x^2}}{}(delta)\right|.$$

$$\left| \sqrt{\pi}\,\mathrm{erfc}\, x \right|$$

That is, the relative error in the argument, x, is amplified by a factor $\frac{2xe^{-x^2}}{\sqrt{\pi}\,\mathrm{erfc}\, x}$ in the result.

The behaviour of this factor is shown in Figure 1.

Figure 1

Please see figure in printed Reference Manual

It should be noted that near x=0 this factor behaves as $\frac{2x}{\sqrt{\pi}}$ and hence the accuracy is largely determined by the machine precision. Also for large negative x, where the factor is $\sim \frac{xe^{-x^2}}{\sqrt{\pi}}$, accuracy is mainly limited by machine precision.

However, for large positive x, the factor becomes $\sim 2x^2$ and to an extent relative accuracy is necessarily lost. The absolute accuracy E is given by

$$E \simeq \frac{2xe^{-x^2}}{\sqrt{\pi}}\delta$$

so absolute accuracy is guaranteed for all x.

8. Further Comments

16.6.11 Returns the value of the Bessel Function $Y_0(x)$

— nags.ht —

```
\begin{page}{manpageXXs17acf}{NAG Documentation: s17acf}
\beginscroll
\begin{verbatim}
```

```
S17ACF(3NAG)      Foundation Library (12/10/92)      S17ACF(3NAG)
```

```
S17 -- Approximations of Special Functions                 S17ACF
        S17ACF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17ACF returns the value of the Bessel Function $Y_0(x)$, via the routine name.

2. Specification

```
       DOUBLE PRECISION FUNCTION S17ACF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Bessel Function of the second kind $Y_0(x)$.

Note: $Y_0(x)$ is undefined for $x<=0$ and the routine will fail for such arguments.

The routine is based on four Chebyshev expansions:

For $0<x<=8$,

$$Y_0(x)=\frac{2}{(pi)}\ln x\sum_{r=0}a_rT_r(t)+\sum_{r=0}b_rT_r(t), \text{ with } t=2\left(\frac{x}{8}\right)^2-1,$$

For $x>8$,

```
                /   2  {        (   (pi))        (   (pi))}
         Y (x)=  /  -----{P (x)sin(x- ----)+Q (x)cos(x- ----)}
          0    \/   (pi)x{ 0      (    4  )  0      (    4  )}

               --'
where P (x)= >   c T (t),
       0     --   r r
             r=0
                                        2
           8 --'                 ( 8)
and Q (x)= - >   d T (t), with t=2( -) -1.
     0     x --   r r            ( x)
             r=0

                          2  (  ( x)        )
For x near zero, Y (x)~= ----(ln( -)+(gamma)), where (gamma)
                  0      (pi)(  ( 2)        )
denotes Euler's constant. This approximation is used when x is
sufficiently small for the result to be correct to machine
precision.

For very large x, it becomes impossible to provide results with
any reasonable accuracy (see Section 7), hence the routine fails.
Such arguments contain insufficient information to determine the

                                                       / 2
phase of oscillation of Y (x); only the amplitude,   /  -, can be
                         0                          \/   x
determined and this is returned on soft failure. The range for
which this occurs is roughly related to the machine precision:
the routine will fail if x>~1/machine precision (see the Users'
Note for your implementation for details).

4. References

      for Mathematical Functions. HMSO.

5. Parameters

 1:  X -- DOUBLE PRECISION                                  Input
     On entry: the argument x of the function. Constraint: X > 0.
     0.

 2:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
```

familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
X is too large. On soft failure the routine returns the amplitude of the Y_0 oscillation, \/2/(pi)x.

IFAIL= 2
X <= 0.0, Y_0 is undefined. On soft failure the routine returns zero.

7. Accuracy

Let (delta) be the relative error in the argument and E be the absolute error in the result. (Since $Y_0(x)$ oscillates about zero, absolute error and not relative error is significant, except for very small x.)

If (delta) is somewhat larger than the machine representation error (e.g. if (delta) is due to data errors etc), then E and (delta) are approximately related by

E~=|xY_1(x)|(delta)

(provided E is also within machine bounds). Figure 1 displays the behaviour of the amplification factor |xY_1(x)|.

Figure 1
Please see figure in printed Reference Manual

However, if (delta) is of the same order as the machine representation errors, then rounding errors could make E slightly larger than the above relation predicts.

For very small x, the errors are essentially independent of (delta) and the routine should provide relative accuracy bounded by the machine precision.

```
          For very large x, the above relation ceases to apply. In this

                           /   2     (   (pi))                  /   2
          region, Y (x)~=  /  -----sin(x- ----). The amplitude   /  -----
                   0     \/   (pi)x   (    4  )               /   (pi)x
          can be calculated with reasonable accuracy for all x, but
             (   (pi))              (pi)
          sin(x- ----) cannot. If x- ---- is written as 2N(pi)+(theta)
             (    4  )               4
                                                              (   (pi))
          where N is an integer and 0<=(theta)<2(pi), then sin(x- ----) is
                                                              (    4  )
                                                  -1
          determined by (theta) only. If x>~(delta)   , (theta) cannot be
          determined with any accuracy at all. Thus if x is greater than,
          or of the order of the inverse of machine precision, it is
          impossible to calculate the phase of Y (x) and the routine must
                                               0
          fail.

          8. Further Comments

          For details of the time taken by the routine see the Users' Note
          for your implementation.

          9. Example

          The example program reads values of the argument x from a file,
          evaluates the function at each value of x and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

     S17ADF(3NAG)      Foundation Library (12/10/92)      S17ADF(3NAG)

          S17 -- Approximations of Special Functions                S17ADF
                  S17ADF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          S17ADF returns the value of the Bessel Function Y (x), via the
                                                           1
          routine name.

          2. Specification

                 DOUBLE PRECISION FUNCTION S17ADF (X, IFAIL)
                 INTEGER          IFAIL
                 DOUBLE PRECISION X

          3. Description

          This routine evaluates an approximation to the Bessel Function of
          the second kind Y (x).
                           1

          Note: Y (x) is undefined for x<=0 and the routine will fail for
                 1
          such arguments.

          The routine is based on four Chebyshev expansions:

          For 0<x<=8,

                        2      x --'           2     x --'
                Y (x)= ----lnx - >   a T (t)- ----x+ - >   b T (t) , with t
                 1     (pi)    8 --   r r     (pi)   8 --   r r
                                   r=0                   r=0
                            2
                          ( x)
                       =2( -) -1;
```

```
( 8)
```

For $x>8$,

$$Y_1(x)=\sqrt{\frac{2}{\pi x}}\left\{P_1(x)\sin\left(x-3\frac{\pi}{4}\right)+Q_1(x)\cos\left(x-3\frac{\pi}{4}\right)\right\}$$

where $P_1(x)=\sum_{r=0}{}' c_r T_r(t)$,

and $Q_1(x)=\frac{8}{x}\sum_{r=0}{}' d_r T_r(t)$, with $t=2\left(\frac{8}{x}\right)^2-1$.

For x near zero, $Y_1(x)\simeq-\frac{2}{\pi x}$. This approximation is used when x is sufficiently small for the result to be correct to machine precision. For extremely small x, there is a danger of overflow in calculating $-\frac{2}{\pi x}$ and for such arguments the routine will fail.

For very large x, it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the

phase of oscillation of $Y_1(x)$, only the amplitude, $\sqrt{\frac{2}{\pi x}}$, can be determined and this is returned on soft failure. The range for which this occurs is roughly related to machine precision; the routine will fail if $x\gtrsim 1/\text{machine precision}$ (see the Users' Note for your implementation for details).

[2] Clenshaw C W (1962) Mathematical Tables. Chebyshev Series for Mathematical Functions. HMSO.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function. Constraint: X > 0. 0.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
X is too large. On soft failure the routine returns the amplitude of the Y_1 oscillation, $\sqrt{\frac{2}{\pi x}}$.

IFAIL= 2
X <= 0.0, Y_1 is undefined. On soft failure the routine returns zero.

IFAIL= 3
X is too close to zero, there is a danger of overflow. On soft failure, the routine returns the value of $Y_1(x)$ at the smallest valid argument.

7. Accuracy

Let (delta) be the relative error in the argument and E be the absolute error in the result. (Since $Y_1(x)$ oscillates about zero, absolute error and not relative error is significant, except for very small x.)

If (delta) is somewhat larger than the machine precision (e.g. if (delta) is due to data errors etc), then E and (delta) are approximately related by:

$$E \simeq |xY_0(x)-Y_1(x)|\delta$$

(provided E is also within machine bounds). Figure 1 displays the behaviour of the amplification factor $|xY_0(x)-Y_1(x)|$.

Figure 1
Please see figure in printed Reference Manual

However, if δ is of the same order as machine precision, then rounding errors could make E slightly larger than the above relation predicts.

For very small x, absolute error becomes large, but the relative error in the result is of the same order as δ.

For very large x, the above relation ceases to apply. In this region, $Y_1(x) \simeq \frac{2\pi}{x}\sin\left(x-\frac{3\pi}{4}\right)$. The amplitude $\frac{2\pi}{x}$ can be calculated with reasonable accuracy for all x, but $\sin\left(x-\frac{3\pi}{4}\right)$ cannot. If $x-\frac{3\pi}{4}$ is written as $2N\pi+\theta$ where N is an integer and $0\le\theta<2\pi$, then $\sin\left(x-\frac{3\pi}{4}\right)$ is determined by θ only. If $x>\delta^{-1}$, θ cannot be determined with any accuracy at all. Thus if x is greater than, or of the order of, the inverse of the machine precision, it is impossible to calculate the phase of $Y_1(x)$ and the routine must fail.

8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation

     S17AEF(3NAG)      Foundation Library (12/10/92)      S17AEF(3NAG)

          S17 -- Approximations of Special Functions                S17AEF
                  S17AEF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          S17AEF returns the value of the Bessel Function J (x), via the
                                                           0
          routine name.

          2. Specification

                 DOUBLE PRECISION FUNCTION S17AEF (X, IFAIL)
                 INTEGER          IFAIL
                 DOUBLE PRECISION X

          3. Description

          This routine evaluates an approximation to the Bessel Function of
          the first kind J (x).
                          0
```

Note: $J_0(-x)=J_0(x)$, so the approximation need only consider $x>=0$.

The routine is based on three Chebyshev expansions:

For $0<x<=8$,

$$J_0(x)=\sum_{r=0}{}' a_r T_r(t), \text{ with } t=2\left(\frac{x}{8}\right)^2-1.$$

For $x>8$,

$$J_0(x)=\sqrt{\frac{2}{(\pi)x}}\left\{P_0(x)\cos\left(x-\frac{\pi}{4}\right)-Q_0(x)\sin\left(x-\frac{\pi}{4}\right)\right\}$$

$$\text{where } P_0(x) = \sum_{r=0}{}' b_r T_r(t),$$

$$\text{and } Q_0(x) = \frac{8}{x}\sum_{r=0}{}' c_r T_r(t), \text{ with } t=2\left(\frac{8}{x}\right)^2-1.$$

For x near zero, $J_0(x)\simeq 1$. This approximation is used when x is sufficiently small for the result to be correct to machine precision.

For very large x, it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the

phase of oscillation of $J_0(x)$; only the amplitude, $\sqrt{\frac{2}{(\pi)|x|}}$, can be determined and this is returned on soft failure. The range for which this occurs is roughly related to the machine precision; the routine will fail if $|x|\gtrsim 1/\text{machine precision}$ (see the Users' Note for your implementation).

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
X is too large. On soft failure the routine returns the

amplitude of the J_0 oscillation, $\sqrt{\frac{2}{\pi|x|}}$.

7. Accuracy

Let δ be the relative error in the argument and E be the absolute error in the result. (Since $J_0(x)$ oscillates about zero, absolute error and not relative error is significant.)

If δ is somewhat larger than the machine precision (e.g. if δ is due to data errors etc), then E and δ are approximately related by:

$$E \simeq |xJ_1(x)|\delta$$

(provided E is also within machine bounds). Figure 1 displays the behaviour of the amplification factor $|xJ_1(x)|$.

Figure 1

```
                  Please see figure in printed Reference Manual

         However, if (delta) is of the same order as machine precision,
         then rounding errors could make E slightly larger than the above
         relation predicts.

         For very large x, the above relation ceases to apply. In this

                           /    2      (   (pi))
         region, J (x)~=  /  -------cos(x- ----). The amplitude
                  0     \/   (pi)|x|   (    4  )

            /    2
           /  ------- can be calculated with reasonable accuracy for all x
         \/   (pi)|x|
               (   (pi))               (pi)
         but cos(x- ----) cannot. If x- ---- is written as
               (    4  )                4
         2N(pi)+(theta) where N is an integer and 0 <= (theta) < 2(pi),
                (   (pi))                                           -1
         then cos(x- ----) is determined by (theta) only. If x>~(delta)   ,
                (    4  )
         (theta) cannot be determined with any accuracy at all. Thus if x
         is greater than, or of the order of, the inverse of the machine
         precision, it is impossible to calculate the phase of J (x) and
                                                                0
         the routine must fail.

         8. Further Comments

         For details of the time taken by the routine see the Users' Note
         for your implementation.

         9. Example

                                                           1
          routine name.

          2. Specification

                 DOUBLE PRECISION FUNCTION S17AFF (X, IFAIL)
                 INTEGER          IFAIL
                 DOUBLE PRECISION X

          3. Description

          This routine evaluates an approximation to the Bessel Function of
          the first kind J (x).
                          1

          Note: J (-x)=-J (x), so the approximation need only consider x>=0
                 1       1

          The routine is based on three Chebyshev expansions:

          For 0<x<=8,                                  2
                       x --'                       ( x)
                J (x)= - >   a T (t) , with t=2( -) -1.
                 1     8 --   r r                  ( 8)
```

r=0

For $x>8$,

$$J_1(x)=\sqrt{\frac{2}{\pi x}}\left\{P_1(x)\cos\left(x-\frac{3\pi}{4}\right)-Q_1(x)\sin\left(x-\frac{3\pi}{4}\right)\right\}$$

where $P_1(x)=\sum_{r=0}{}' b_r T_r(t)$,

and $Q_1(x)=\frac{8}{x}\sum_{r=0}{}' c_r T_r(t)$, with $t=2\left(\frac{8}{x}\right)^2-1$.

For x near zero, $J_1(x)\simeq\frac{x}{2}$. This approximation is used when x is sufficiently small for the result to be correct to machine precision.

For very large x, it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the phase of oscillation of $J_1(x)$; only the amplitude, $\sqrt{\frac{2}{\pi|x|}}$, can be determined and this is returned on soft failure. The range for which this occurs is roughly related to the machine precision; the routine will fail if $|x|\gtrsim 1/\text{machine precision}$ (see the Users' Note for your implementation for details).

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

X is too large. On soft failure the routine returns the amplitude of the J_1 oscillation, $\sqrt{\frac{2}{(pi)|x|}}$.

7. Accuracy

Let (delta) be the relative error in the argument and E be the absolute error in the result. (Since $J_1(x)$ oscillates about zero, absolute error and not relative error is significant.)

If (delta) is somewhat larger than machine precision (e.g. if (delta) is due to data errors etc), then E and (delta) are approximately related by:

$$E\sim=|xJ_0(x)-J_1(x)|(delta)$$

(provided E is also within machine bounds). Figure 1 displays the behaviour of the amplification factor $|xJ_0(x)-J_1(x)|$.

Figure 1
Please see figure in printed Reference Manual

However, if (delta) is of the same order as machine precision, then rounding errors could make E slightly larger than the above relation predicts.

For very large x, the above relation ceases to apply. In this

```
                   /    2      (   3(pi))
region, J (x)~=  /  -------cos(x- -----). The amplitude
         1     \/   (pi)|x|   (     4  )

   /    2
  /  ------- can be calculated with reasonable accuracy for all x
\/   (pi)|x|
       (   3(pi))              3(pi)
but cos(x- -----) cannot. If x- ----- is written as
       (     4  )                4
2N(pi)+(theta) where N is an integer and 0<=(theta)<2(pi), then
   (   3(pi))                                          -1
cos(x- -----) is determined by (theta) only. If x>~(delta)  ,
   (     4  )
(theta) cannot be determined with any accuracy at all. Thus if x
is greater than, or of the order of, machine precision, it is
impossible to calculate the phase of J (x) and the routine must
                                      1
fail.

          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          S17AGF returns a value for the Airy function, Ai(x), via the
          routine name.

          2. Specification

                 DOUBLE PRECISION FUNCTION S17AGF (X, IFAIL)
                 INTEGER          IFAIL
                 DOUBLE PRECISION X

          3. Description

          This routine evaluates an approximation to the Airy function,
          Ai(x). It is based on a number of Chebyshev expansions:

          For x<-5,

                                      a(t)sinz-b(t)cosz
                               Ai(x)= -----------------
                                               1/4
                                           (-x)

                   (pi)  2  /  3
          where z= ----+ -\/ -x  , and a(t) and b(t) are expansions in the
                    4    3
                           3
                      ( 5)
          variable t=-2( -) -1.
                      ( x)

          For -5<=x<=0,
```

$$Ai(x)=f(t)-xg(t),$$

where f and g are expansions in $t=-2\left(\frac{x}{5}\right)^3-1$.

For $0<x<4.5$,

$$Ai(x)=e^{-3x/2}y(t),$$

where y is an expansion in $t=4x/9-1$.

For $4.5<=x<9$,

$$Ai(x)=e^{-5x/2}u(t),$$

where u is an expansion in $t=4x/9-3$.

For $x>=9$,

$$Ai(x)=\frac{e^{-z}v(t)}{x^{1/4}},$$

where $z=\frac{2}{3}\sqrt{x^3}$ and v is an expansion in $t=2\left(\frac{18}{z}\right)-1$.

For $|x|<$ the machine precision, the result is set directly to Ai(0). This both saves time and guards against underflow in intermediate calculations.

For large negative arguments, it becomes impossible to calculate the phase of the oscillatory function with any precision and so the routine must fail. This occurs if $x<-\left(\frac{3}{2(\epsilon)}\right)^{2/3}$, where (ϵ) is the machine precision.

For large positive arguments, where Ai decays in an essentially exponential manner, there is a danger of underflow so the routine must fail.

```

      Functions. Dover Publications.

5. Parameters

 1:  X -- DOUBLE PRECISION                                 Input
     On entry: the argument x of the function.

 2:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.
     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     X is too large and positive. On soft failure, the routine
     returns zero.

IFAIL= 2
     X is too large and negative. On soft failure, the routine
     returns zero.

7. Accuracy

For negative arguments the function is oscillatory and hence
absolute error is the appropriate measure. In the positive region
the function is essentially exponential-like and here relative
error is appropriate. The absolute error, E, and the relative
error, (epsilon), are related in principle to the relative error
in the argument, (delta), by

                                       | xAi'(x)|
       E~=|xAi'(x)|(delta), (epsilon)~=| -------|(delta).
                                       |  Ai(x) |

In practice, approximate equality is the best that can be
expected. When (delta), (epsilon) or E is of the order of the
machine precision, the errors in the result will be somewhat
larger.

For small x, errors are strongly damped by the function and hence
will be bounded by the machine precision.
```

```
          For moderate negative x, the error behaviour is oscillatory but
          the amplitude of the error grows like

                                                 5/4
                                (    E   )  |x|
                      amplitude ( -------)~ ------.
                                ( (delta))
                                            \/(pi)

                                                            2  /   3
          However the phase error will be growing roughly like  -\/ |x|
                                                            3
          and hence all accuracy will be lost for large negative arguments
          due to the impossibility of calculating sin and cos to any

                       2  /   3     1
          accuracy if  -\/ |x| > -------.
                       3         (delta)

          For large positive arguments, the relative error amplification is
          considerable:

                                 (epsilon)   / 3
                                 ---------~\/ x .
                                  (delta)

          This means a loss of roughly two decimal places accuracy for
          arguments in the region of 20. However very large arguments are
          not possible due to the danger of setting underflow and so the
          errors are limited in practice.

          8. Further Comments

          None.

          9. Example

          The example program reads values of the argument x from a file,
          evaluates the function at each value of x and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

          S17 -- Approximations of Special Functions                S17AHF
                  S17AHF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          S17AHF returns a value of the Airy function, Bi(x), via the
          routine name.

          2. Specification

                 DOUBLE PRECISION FUNCTION S17AHF (X, IFAIL)
                 INTEGER          IFAIL
                 DOUBLE PRECISION X

          3. Description

          This routine evaluates an approximation to the Airy function
          Bi(x). It is based on a number of Chebyshev expansions.

          For x<-5,

                                       a(t)cosz+b(t)sinz
                                Bi(x)= -----------------,
```

$$(-x)^{1/4}$$

where $z=\frac{\pi}{4}+\frac{2}{3}\sqrt{-x^3}$ and a(t) and b(t) are expansions in the variable $t=-2\left(\frac{5}{x}\right)^3-1$.

For $-5<=x<=0$,

$$Bi(x)=\sqrt{3}(f(t)+xg(t)),$$

where f and g are expansions in $t=-2\left(\frac{x}{5}\right)^3-1$.

For $0<x<4.5$,

$$Bi(x)=e^{11x/8}y(t),$$

where y is an expansion in $t=4x/9-1$.

For $4.5<=x<=9$,

$$Bi(x)=e^{5x/2}v(t),$$

where v is an expansion in $t=4x/9-3$.

For $x>=9$,

$$Bi(x)=\frac{e^z u(t)}{x^{1/4}},$$

where $z=\frac{2}{3}\sqrt{x^3}$ and u is an expansion in $t=2\left(\frac{18}{z}\right)-1$.

For |x|< the machine precision, the result is set directly to Bi(0). This both saves time and avoids possible intermediate underflows.

For large negative arguments, it becomes impossible to calculate the phase of the oscillating function with any accuracy so the routine must fail. This occurs if $x < -\left(\frac{3}{2(\epsilon)}\right)^{2/3}$, where (epsilon) is the machine precision.

For large positive arguments, there is a danger of causing overflow since Bi grows in an essentially exponential manner, so the routine must fail.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
X is too large and positive. On soft failure, the routine returns zero.

IFAIL= 2
X is too large and negative. On soft failure, the routine returns zero.

7. Accuracy

For negative arguments the function is oscillatory and hence

```
absolute error is the appropriate measure. In the positive region
the function is essentially exponential-like and here relative
error is appropriate. The absolute error, E, and the relative
error, (epsilon), are related in principle to the relative error
in the argument, (delta), by

                                   | xBi'(x)|
       E~=|xBi'(x)|(delta), (epsilon)~=| -------|(delta).
                                   |  Bi(x)  |

In practice, approximate equality is the best that can be
expected. When (delta), (epsilon) or E is of the order of the
machine precision, the errors in the result will be somewhat
larger.

For small x, errors are strongly damped and hence will be bounded
essentially by the machine precision.

For moderate to large negative x, the error behaviour is clearly
oscillatory but the amplitude of the error grows like amplitude
              5/4
(    E   )  |x|
( -------)~ ------.
( (delta))
          \/(pi)

                                                    2  /   3
However the phase error will be growing roughly as  -\/ |x|  and
                                                    3
hence all accuracy will be lost for large negative arguments.

This is due to the impossibility of calculating sin and cos to

                 2  /   3     1
any accuracy if  -\/ |x| > -------.
                 3        (delta)

For large positive arguments, the relative error amplification is
considerable:

                        (epsilon)   / 3
                        ---------~\/ x .
                         (delta)

This means a loss of roughly two decimal places accuracy for
```

```
          arguments in the region of 20. However very large arguments are
          not possible due to the danger of causing overflow and errors are
          therefore limited in practice.

          8. Further Comments

          For details of the time taken by the routine see the Users' Note
          for your implementation.

          9. Example

          The example program reads values of the argument x from a file,
          evaluates the function at each value of x and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

                  S17AJF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose
```

S17AJF returns a value of the derivative of the Airy function Ai(x), via the routine name.

2. Specification

```
      DOUBLE PRECISION FUNCTION S17AJF (X, IFAIL)
      INTEGER          IFAIL
      DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the derivative of the Airy function Ai(x). It is based on a number of Chebyshev expansions.

For $x<-5$,

$$Ai'(x)=\sqrt[4]{-x}\left[a(t)\cos z+\frac{b(t)}{\zeta}\sin z\right],$$

where $z=\frac{\pi}{4}+\zeta$, $\zeta=\frac{2}{3}\sqrt{-x^3}$ and $a(t)$ and $b(t)$ are expansions in variable $t=-2\left(\frac{5}{x}\right)^3-1$.

For $-5<=x<=0$,

$$Ai'(x)=x^2f(t)-g(t),$$

where f and g are expansions in $t=-2\left(\frac{x}{5}\right)^3-1$.

For $0<x<4.5$,

$$Ai'(x)=e^{-11x/8}y(t),$$

where $y(t)$ is an expansion in $t=4\left(\frac{x}{9}\right)-1$.

For $4.5<=x<9$,

$$Ai'(x)=e^{-5x/2}v(t),$$

where v(t) is an expansion in $t=4\left(\frac{x}{9}\right)-3$.

For x>=9,

$$Ai'(x)=\sqrt[4]{-x}e^{-z}u(t),$$

where $z=\frac{2}{3}\sqrt{x^3}$ and u(t) is an expansion in $t=2\left(\frac{18}{z}\right)-1$.

For |x|< the square of the machine precision, the result is set directly to Ai'(0). This both saves time and avoids possible intermediate underflows.

For large negative arguments, it becomes impossible to calculate a result for the oscillating function with any accuracy and so the routine must fail. This occurs for $x<-\left(\frac{\sqrt{\pi}}{\epsilon}\right)^{4/7}$, where ϵ is the machine precision.

For large positive arguments, where Ai' decays in an essentially exponential manner, there is a danger of underflow so the routine must fail.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

```
     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     X is too large and positive. On soft failure, the routine
     returns zero.

IFAIL= 2
     X is too large and negative. On soft failure, the routine
     returns zero.

7. Accuracy

For negative arguments the function is oscillatory and hence
absolute error is the appropriate measure. In the positive region
the function is essentially exponential in character and here
relative error is needed. The absolute error, E, and the relative
error, (epsilon), are related in principle to the relative error
in the argument, (delta), by

                                       |  2     |
         2                             | x Ai(x)|
      E~=|x Ai(x)|(delta)    (epsilon)~=| -------|(delta).
                                       | Ai'(x) |

In practice, approximate equality is the best that can be
expected. When (delta), (epsilon) or E is of the order of the
machine precision, the errors in the result will be somewhat
larger.

For small x, positive or negative, errors are strongly attenuated
by the function and hence will be roughly bounded by the machine
precision.

For moderate to large negative x, the error, like the function,
is oscillatory; however the amplitude of the error grows like

                              7/4
                           |x|
                           ------.

                           \/(pi)

Therefore it becomes impossible to calculate the function with
```

```
                            7/4  \/(pi)
          any accuracy if |x|   > -------.
                                 (delta)

          For large positive x, the relative error amplification is
          considerable:

                                 (epsilon)    / 3
                                 ---------~=\/ x .
                                  (delta)

          However, very large arguments are not possible due to the danger
          of underflow. Thus in practice error amplification is limited.

          8. Further Comments

          None.

          9. Example

          The example program reads values of the argument x from a file,
          evaluates the function at each value of x and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

S17 -- Approximations of Special Functions                 S17AKF
        S17AKF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S17AKF returns a value for the derivative of the Airy function
Bi(x), via the routine name.

2. Specification

       DOUBLE PRECISION FUNCTION S17AKF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X

3. Description

This routine calculates an approximate value for the derivative
of the Airy function Bi(x). It is based on a number of Chebyshev
expansions.

For x<-5,

                     4   [            b(t)     ]
               Bi'(x)=\/-x[-a(t)sinz+ ------cosz],
                         [           (zeta)    ]

         (pi)                2  /  3
where z= ----+(zeta),(zeta)= -\/ -x  and a(t) and b(t) are
          4                  3
                                 3
                              ( 5)
expansions in the variable t=-2( -) -1.
                              ( x)

For -5<=x<=0,

                                2
                    Bi'(x)=\/3(x f(t)+g(t)),
                                        3
                                     ( x)
where f and g are expansions in t=-2( -) -1.
```

$$(5)$$

For $0<x<4.5$,

$$Bi'(x)=e^{3x/2}y(t),$$

where $y(t)$ is an expansion in $t=4x/9-1$.

For $4.5<=x<9$,

$$Bi'(x)=e^{21x/8}u(t),$$

where $u(t)$ is an expansion in $t=4x/9-3$.

For $x>=9$,

$$Bi'(x)=\sqrt[4]{x}e^{z}v(t),$$

where $z=\frac{2}{3}\sqrt{x^3}$ and $v(t)$ is an expansion in $t=2\left(\frac{18}{z}\right)-1$.

For $|x|<$ the square of the machine precision, the result is set directly to $Bi'(0)$. This saves time and avoids possible underflows in calculation.

For large negative arguments, it becomes impossible to calculate a result for the oscillating function with any accuracy so the routine must fail. This occurs for $x<-\left(\frac{\sqrt{\pi}}{\epsilon}\right)^{4/7}$, where ϵ is the machine precision.

For large positive arguments, where Bi' grows in an essentially exponential manner, there is a danger of overflow so the routine must fail.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

```
 1:  X -- DOUBLE PRECISION                                  Input
     On entry: the argument x of the function.

 2:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.
     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     X is too large and positive. On soft failure the routine
     returns zero.

IFAIL= 2
     X is too large and negative. On soft failure the routine
     returns zero.

7. Accuracy

For negative arguments the function is oscillatory and hence
absolute error is appropriate. In the positive region the
function has essentially exponential behaviour and hence relative
error is needed. The absolute error, E, and the relative error
(epsilon), are related in principle to the relative error in the
argument (delta), by

                                       |  2     |
           2                           | x Bi(x)|
      E~=|x Bi(x)|(delta)    (epsilon)~=| -------|(delta).
                                       | Bi'(x)  |

In practice, approximate equality is the best that can be
expected. When (delta), (epsilon) or E is of the order of the
machine precision, the errors in the result will be somewhat
larger.

For small x, positive or negative, errors are strongly attenuated
by the function and hence will effectively be bounded by the
machine precision.

For moderate to large negative x, the error is, like the
function, oscillatory. However, the amplitude of the absolute
                     7/4
                  |x|
          error grows like  ------. Therefore it becomes impossible to

                            \/(pi)

                                                       7/4  \/(pi)
          calculate the function with any accuracy if |x|   > -------.
                                                            (delta)

          For large positive x, the relative error amplification is

                         (epsilon)   / 3
          considerable:  ---------~\/ x . However, very large arguments are
                          (delta)
          not possible due to the danger of overflow. Thus in practice the
          actual amplification that occurs is limited.

          8. Further Comments

          None.

          9. Example

          The example program reads values of the argument x from a file,
          evaluates the function at each value of x and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

S17 -- Approximations of Special Functions S17DCF

S17DCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17DCF returns a sequence of values for the Bessel functions $Y_{(nu)+n}(z)$ for complex z, non-negative (nu) and n=0,1,...,N-1, with an option for exponential scaling.

2. Specification

```
      SUBROUTINE S17DCF (FNU, Z, N, SCALE, CY, NZ, CWRK, IFAIL)
      INTEGER             N, NZ, IFAIL
      DOUBLE PRECISION    FNU
      COMPLEX(KIND(1.0D0)) Z, CY(N), CWRK(N)
      CHARACTER*1         SCALE
```

3. Description

This subroutine evaluates a sequence of values for the Bessel function $Y_{(nu)}(z)$, where z is complex, -(pi) < arg z <= (pi), and (nu) is the real, non-negative order. The N-member sequence is generated for orders (nu), (nu)+1,...,(nu)+N-1. Optionally, the sequence is scaled by the factor $e^{-|Im\ z|}$.

Note: although the routine may not be called with (nu) less than zero, for negative orders the formula $Y_{-(nu)}(z)=Y_{(nu)}(z)\cos((pi)(nu))+J_{(nu)}(z)\sin((pi)(nu))$ may be used (for the Bessel function $J_{(nu)}(z)$, see S17DEF).

The routine is derived from the routine CBESY in Amos [2]. It is based on the relation $Y_{(nu)}(z)=\frac{H^{(1)}_{(nu)}(z)-H^{(2)}_{(nu)}(z)}{}$, where $H^{(1)}_{(nu)}(z)$

(nu)   2i   (nu)

and $H_{(nu)}^{(2)}(z)$ are the Hankel functions of the first and second kinds respectively (see S17DLF).

When N is greater than 1, extra values of $Y_{(nu)}(z)$ are computed using recurrence relations.

For very large |z| or ((nu)+N-1), argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller |z| or ((nu)+N-1), the computation is performed but results are accurate to less than half of machine precision. If |z| is very small, near the machine underflow threshold, or ((nu)+N-1) is too large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

4. References

[2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

5. Parameters

1: FNU -- DOUBLE PRECISION Input
On entry: the order, (nu), of the first member of the sequence of functions. Constraint: FNU >= 0.0.

2: Z -- COMPLEX(KIND(1.0D0)) Input
On entry: the argument, z, of the functions. Constraint: Z /= (0.0, 0.0).

3: N -- INTEGER Input
On entry: the number, N, of members required in the sequence $Y_{(nu)}(z), Y_{(nu)+1}(z),...,Y_{(nu)+N-1}(z)$. Constraint: N >= 1.

4: SCALE -- CHARACTER*1 Input
On entry: the scaling option.

If SCALE = 'U', the results are returned unscaled.

If SCALE = 'S', the results are returned scaled by the
-|Imz|

```
    factor e      . Constraint: SCALE = 'U' or 'S'.

5:  CY(N) -- COMPLEX(KIND(1.0D)) array                  Output
    On exit: the N required function values: CY(i) contains
    Y        (z), for i=1,2,...,N.
     (nu)+i-1

6:  NZ -- INTEGER                                       Output
    On exit: the number of components of CY that are set to zero
    due to underflow. The positions of such components in the
    array CY are arbitrary.

7:  CWRK(N) -- COMPLEX(KIND(1.0D)) array             Workspace

8:  IFAIL -- INTEGER                              Input/Output
    On entry: IFAIL must be set to 0, -1 or 1. For users not
    familiar with this parameter (described in the Essential
    Introduction) the recommended value is 0.

    On exit: IFAIL = 0 unless the routine detects an error (see
    Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry FNU < 0.0,

     or       Z = (0.0, 0.0),

     or       N < 1,

     or       SCALE /= 'U' or 'S'.

IFAIL= 2
     No computation has been performed due to the likelihood of
     overflow, because ABS(Z) is less than a machine-dependent
     threshold value (given in the Users' Note for your
     implementation).

IFAIL= 3
     No computation has been performed due to the likelihood of
     overflow, because FNU + N - 1 is too large - how large
     depends on Z as well as the overflow threshold of the
     machine.
```

```
IFAIL= 4
     The computation has been performed, but the errors due to
     argument reduction in elementary functions make it likely
     that the results returned by S17DCF are accurate to less
     than half of machine precision. This error exit may occur if
     either ABS(Z) or FNU + N - 1 is greater than a machine-
     dependent threshold value (given in the Users' Note for
     your implementation).

IFAIL= 5
     No computation has been performed because the errors due to
     argument reduction in elementary functions mean that all
     precision in results returned by S17DCF would be lost. This
     error exit may occur if either ABS(Z) or FNU + N - 1 is
     greater than a machine-dependent threshold value (given in
     the Users' Note for your implementation).

IFAIL= 6
     No results are returned because the algorithm termination
     condition has not been met. This may occur because the
     parameters supplied to S17DCF would have caused overflow or
     underflow.

7. Accuracy

All constants in subroutine S17DCF are given to approximately 18
digits of precision. Calling the number of digits of precision in
the floating-point arithmetic being used t, then clearly the
maximum number of correct digits in the results obtained is
limited by p=min(t,18). Because of errors in argument reduction
when computing elementary functions inside S17DCF, the actual
number of correct digits is limited, in general, by p-s, where
s~max(1,|log  |z||,|log  (nu)|) represents the number of digits
            10         10
lost due to the argument reduction. Thus the larger the values of
|z| and (nu), the less the precision in the result. If S17DCF is
called with N>1, then computation of function values via
recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are
computed by calls to S17DCF with different base values of (nu)
and different N, the computed values may not agree exactly.
Empirical tests with modest values of (nu) and z have shown that
the discrepancy is limited to the least significant 3-4 digits of
precision.

8. Further Comments

The time taken by the routine for a call of S17DCF is
approximately proportional to the value of N, plus a constant. In
```

```
          general it is much cheaper to call S17DCF with N greater than 1,
          rather than to make N separate calls to S17DCF.

          Paradoxically, for some values of z and (nu), it is cheaper to
          call S17DCF with a larger value of N than is required, and then
          discard the extra function values returned. However, it is not
          possible to state the precise circumstances in which this is
          likely to occur. It is due to the fact that the base value used
          to start recurrence may be calculated in different regions for
          different N, and the costs in each region may differ greatly.

          Note that if the function required is Y (x) or Y (x), i.e., (nu)
                                                 0       1
          = 0.0 or 1.0, where x is real and positive, and only a single
          unscaled function value is required, then it may be much cheaper
          to call S17ACF or S17ADF respectively.

          9. Example

          The example program prints a caption and then proceeds to read
          sets of data from the input data stream. The first datum is a
          value for the order FNU, the second is a complex value for the
          argument, Z, and the third is a value for the parameter SCALE.
          The program calls the routine with N = 2 to evaluate the function
          for orders FNU and FNU + 1, and it prints the results. The
          process is repeated until the end of the input data stream is
          encountered.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

S17 -- Approximations of Special Functions   S17DEF

S17DEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17DEF returns a sequence of values for the Bessel functions $J_{\nu+n}(z)$ for complex z, non-negative ν and n=0,1,...,N-1, with an option for exponential scaling.

2. Specification

```
      SUBROUTINE S17DEF (FNU, Z, N, SCALE, CY, NZ, IFAIL)
      INTEGER              N, NZ, IFAIL
      DOUBLE PRECISION     FNU
      COMPLEX(KIND(1.0D0)) Z, CY(N)
      CHARACTER*1          SCALE
```

3. Description

This subroutine evaluates a sequence of values for the Bessel function $J_{\nu}(z)$, where z is complex, $-\pi < \arg z \le \pi$, and ν is the real, non-negative order. The N-member sequence is generated for orders ν, $\nu+1$,...,$\nu+N-1$. Optionally, the sequence is scaled by the factor $e^{-|\mathrm{Im}\, z|}$.

Note: although the routine may not be called with ν less than zero, for negative orders the formula $J_{-\nu}(z)=J_{\nu}(z)\cos(\pi\nu)-Y_{\nu}(z)\sin(\pi\nu)$ may be used (for the Bessel function $Y_{\nu}(z)$, see S17DCF).

The routine is derived from the routine CBESJ in Amos [2]. It is based on the relations $J_{\nu}(z)=e^{\nu\pi i/2}I_{\nu}(-iz)$, $\mathrm{Im}\, z\ge0.0$ and $J_{\nu}(z)=e^{-\nu\pi i/2}I_{\nu}(iz)$, $\mathrm{Im}\, z<0.0$.

(nu) (nu)

The Bessel function $I_{(nu)}(z)$ is computed using a variety of techniques depending on the region under consideration.

When N is greater than 1, extra values of $J_{(nu)}(z)$ are computed using recurrence relations.

For very large |z| or ((nu)+N-1), argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller |z| or ((nu)+N-1), the computation is performed but results are accurate to less than half of machine precision. If Im z is large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

5. Parameters

1: FNU -- DOUBLE PRECISION Input
On entry: the order, (nu), of the first member of the sequence of functions. Constraint: FNU >= 0.0.

2: Z -- COMPLEX(KIND(1.0D0)) Input
On entry: the argument z of the functions.

3: N -- INTEGER Input
On entry: the number, N, of members required in the sequence $J_{(nu)}(z),J_{(nu)+1}(z),...,J_{(nu)+N-1}(z)$. Constraint: N >= 1.

4: SCALE -- CHARACTER*1 Input
On entry: the scaling option.

If SCALE = 'U', the results are returned unscaled.

If SCALE = 'S', the results are returned scaled by the factor $e^{-|Imz|}$.

Constraint: SCALE = 'U' or 'S'.

5: CY(N) -- COMPLEX(KIND(1.0D)) array Output
On exit: the N required function values: CY(i) contains
$J_{(nu)+i-1}(z)$, for i=1,2,...,N.

6: NZ -- INTEGER Output
On exit: the number of components of CY that are set to zero due to underflow. If NZ > 0, then elements CY(N-NZ+1), CY(N-NZ+2),...,CY(N) are set to zero.

7: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry FNU < 0.0,

or N < 1,

or SCALE /= 'U' or 'S'.

IFAIL= 2
No computation has been performed due to the likelihood of overflow, because Im Z is larger than a machine-dependent threshold value (given in the Users' Note for your implementation). This error exit can only occur when SCALE = 'U'.

IFAIL= 3
The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by S17DEF are accurate to less than half of machine precision. This error exit may occur if either ABS(Z) or FNU + N - 1 is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 4
No computation has been performed because the errors due to

```
     argument reduction in elementary functions mean that all
     precision in results returned by S17DEF would be lost. This
     error exit may occur when either ABS(Z) or FNU + N - 1 is
     greater than a machine-dependent threshold value (given in
     the Users' Note for your implementation).

IFAIL= 5
     No results are returned because the algorithm termination
     condition has not been met. This may occur because the
     parameters supplied to S17DEF would have caused overflow or
     underflow.

7. Accuracy

All constants in subroutine S17DEF are given to approximately 18
digits of precision. Calling the number of digits of precision in
the floating-point arithmetic being used t, then clearly the
maximum number of correct digits in the results obtained is
limited by p=min(t,18). Because of errors in argument reduction
when computing elementary functions inside S17DEF, the actual
number of correct digits is limited, in general, by p-s, where
s~max(1,|log  |(|z|),|log  (nu)|) represents the number of digits
            10           10
lost due to the argument reduction. Thus the larger the values of
|z| and (nu), the less the precision in the result. If S17DEF is
called with N>1, then computation of function values via
recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are
computed by calls to S17DEF with different base values of (nu)
and different N, the computed values may not agree exactly.
Empirical tests with modest values of (nu) and z have shown that
the discrepancy is limited to the least significant 3-4 digits of
precision.

8. Further Comments

The time taken by the routine for a call of S17DEF is
approximately proportional to the value of N, plus a constant. In
general it is much cheaper to call S17DEF with N greater than 1,
rather than to make N separate calls to S17DEF.

Paradoxically, for some values of z and (nu), it is cheaper to
call S17DEF with a larger value of N than is required, and then
discard the extra function values returned. However, it is not
possible to state the precise circumstances in which this is
likely to occur. It is due to the fact that the base value used
to start recurrence may be calculated in different regions for
different N, and the costs in each region may differ greatly.
```

```
          Note that if the function required is J (x) or J (x), i.e., (nu)
                                                 0        1
          = 0.0 or 1.0, where x is real and positive, and only a single
          unscaled function value is required, then it may be much cheaper
          to call S17AEF or S17AFF respectively.

          9. Example

          The example program prints a caption and then proceeds to read
          sets of data from the input data stream. The first datum is a
          value for the order FNU, the second is a complex value for the
          argument, Z, and the third is a value for the parameter SCALE.

          The program calls the routine with N = 2 to evaluate the function
          for orders FNU and FNU + 1, and it prints the results. The
          process is repeated until the end of the input data stream is
          encountered.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

16.6.21 Value of the Airy function $Ai(z)$ or derivative $Ai'(z)$

— nags.ht —

```
\begin{page}{manpageXXs17dgf}{NAG Documentation: s17dgf}
\beginscroll
\begin{verbatim}

     S17DGF(3NAG)      Foundation Library (12/10/92)      S17DGF(3NAG)

          S17 -- Approximations of Special Functions                 S17DGF
                  S17DGF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
```

The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17DGF returns the value of the Airy function Ai(z) or its derivative Ai'(z) for complex z, with an option for exponential scaling.

2. Specification

```
       SUBROUTINE S17DGF (DERIV, Z, SCALE, AI, NZ, IFAIL)
       INTEGER              NZ, IFAIL
       COMPLEX(KIND(1.0D0)) Z, AI
       CHARACTER*1          DERIV, SCALE
```

3. Description

This subroutine returns a value for the Airy function Ai(z) or its derivative Ai'(z), where z is complex, $-\pi < \arg z \le \pi$.

Optionally, the value is scaled by the factor $e^{2z\sqrt{z}/3}$.

The routine is derived from the routine CAIRY in Amos [2]. It is

based on the relations $Ai(z)=\frac{\sqrt{z}K_{1/3}(w)}{\pi\sqrt{3}}$, and $Ai'(z)=\frac{-zK_{2/3}(w)}{\pi/3}$,

where K_{ν} is the modified Bessel function and $w=2z\sqrt{z}/3$.

For very large |z|, argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller |z|, the computation is performed but results are accurate to less than half of machine precision. If Re w is too large, and the unscaled function is required, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

```

```
5. Parameters

 1:  DERIV -- CHARACTER*1                                   Input
     On entry: specifies whether the function or its derivative
     is required.
          If DERIV = 'F', Ai(z) is returned.

          If DERIV = 'D', Ai'(z) is returned.
     Constraint: DERIV = 'F' or 'D'.

 2:  Z -- COMPLEX(KIND(1.0D0))                              Input
     On entry: the argument z of the function.

 3:  SCALE -- CHARACTER*1                                   Input
     On entry: the scaling option.

     If SCALE = 'U', the result is returned unscaled.

     If SCALE = 'S', the result is returned scaled by the factor

      2z\/z/3
     e       . Constraint: SCALE = 'U' or 'S'.

 4:  AI -- COMPLEX(KIND(1.0D0))                            Output
     On exit: the required function or derivative value.

 5:  NZ -- INTEGER                                         Output
     On exit: NZ indicates whether or not AI is set to zero due
     to underflow. This can only occur when SCALE = 'U'.

     If NZ = 0, AI is not set to zero.

     If NZ = 1, AI is set to zero.

 6:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings
```

```
Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry DERIV /= 'F' or 'D'.

     or       SCALE /= 'U' or 'S'.

IFAIL= 2
     No computation has been performed due to the likelihood of

     overflow, because Re w is too large, where w=2Z\/Z/3 -- how
     large depends on Z and the overflow threshold of the
     machine. This error exit can only occur when SCALE = 'U'.

IFAIL= 3
     The computation has been performed, but the errors due to
     argument reduction in elementary functions make it likely
     that the result returned by S17DGF is accurate to less than
     half of machine precision. This error exit may occur if ABS
     (Z) is greater than a machine-dependent threshold value
     (given in the Users' Note for your implementation).

IFAIL= 4
     No computation has been performed because the errors due to
     argument reduction in elementary functions mean that all
     precision in the result returned by S17DGF would be lost.
     This error exit may occur if ABS(Z) is greater than a
     machine-dependent threshold value (given in the Users' Note
     for your implementation).

IFAIL= 5
     No result is returned because the algorithm termination
     condition has not been met. This may occur because the
     parameters supplied to S17DGF would have caused overflow or
     underflow.

7. Accuracy

All constants in subroutine S17DGF are given to approximately 18
digits of precision. Calling the number of digits of precision in
the floating-point arithmetic being used t, then clearly the
maximum number of correct digits in the results obtained is
limited by p=min(t,18). Because of errors in argument reduction
when computing elementary functions inside S17DGF, the actual
number of correct digits is limited, in general, by p-s, where
```

```
          s~max(1,|log  |z||) represents the number of digits lost due to
                      10
          the argument reduction. Thus the larger the value of |z|, the
          less the precision in the result.

          Empirical tests with modest values of z, checking relations
          between Airy functions Ai(z), Ai'(z), Bi(z) and Bi'(z), have
          shown errors limited to the least significant 3-4 digits of
          precision.

          8. Further Comments

          Note that if the function is required to operate on a real
          argument only, then it may be much cheaper to call S17AGF or
          S17AJF.

          9. Example

          The example program prints a caption and then proceeds to read
          sets of data from the input data stream. The first datum is a
          value for the parameter DERIV, the second is a complex value for
          the argument, Z, and the third is a value for the parameter
          SCALE. The program calls the routine and prints the results. The
          process is repeated until the end of the input data stream is
          encountered.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

16.6.22 Value of the Airy function $Bi(z)$ or derivative $Bi'(z)$

— nags.ht —

```
\begin{page}{manpageXXs17dhf}{NAG Documentation: s17dhf}
\beginscroll
\begin{verbatim}

     S17DHF(3NAG)      Foundation Library (12/10/92)      S17DHF(3NAG)
```

```
S17 -- Approximations of Special Functions                S17DHF
        S17DHF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17DHF returns the value of the Airy function Bi(z) or its derivative Bi'(z) for complex z, with an option for exponential scaling.

2. Specification

```
       SUBROUTINE S17DHF (DERIV, Z, SCALE, BI, IFAIL)
       INTEGER             IFAIL
       COMPLEX(KIND(1.0D0)) Z, BI
       CHARACTER*1          DERIV, SCALE
```

3. Description

This subroutine returns a value for the Airy function Bi(z) or its derivative Bi'(z), where z is complex, $-\pi < \arg z \le \pi$.

Optionally, the value is scaled by the factor $e^{|\mathrm{Re}\,(2z\sqrt{z}/3)|}$.

The routine is derived from the routine CBIRY in Amos [2]. It is

based on the relations $\mathrm{Bi}(z)=\frac{\sqrt{z}}{\sqrt{3}}(I_{-1/3}(w)+I_{1/3}(w))$, and

$\mathrm{Bi}'(z)=\frac{z}{\sqrt{3}}(I_{-2/3}(w)+I_{2/3}(w))$, where I_{ν} is the modified Bessel

function and $w=2z\sqrt{z}/3$.

For very large |z|, argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller |z|, the computation is performed but results are accurate to less than half of machine precision. If Re z is too large, and the unscaled function is required, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

[2] Hammersley J M and Handscomb D C (1967) Monte-Carlo Methods. Methuen.

5. Parameters

1: DERIV -- CHARACTER*1 Input

On entry: specifies whether the function or its derivative is required.

If DERIV = 'F', Bi(z) is returned.

If DERIV = 'D', Bi'(z) is returned.

Constraint: DERIV = 'F' or 'D'.

2: Z -- COMPLEX(KIND(1.0D0)) Input

On entry: the argument z of the function.

3: SCALE -- CHARACTER*1 Input

On entry: the scaling option.

If SCALE = 'U', the result is returned unscaled.

If SCALE = 'S', the result is returned scaled by the factor $e^{|Re(2z\sqrt{z}/3)|}$.

Constraint: SCALE = 'U' or 'S'.

4: BI -- COMPLEX(KIND(1.0D0)) Output

On exit: the required function or derivative value.

5: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

```
Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry DERIV /= 'F' or 'D'.

     or       SCALE /= 'U' or 'S'.

IFAIL= 2
     No computation has been performed due to the likelihood of
     overflow, because real(Z) is too large - how large depends
     on the overflow threshold of the machine. This error exit
     can only occur when SCALE = 'U'.

IFAIL= 3
     The computation has been performed, but the errors due to
     argument reduction in elementary functions make it likely
     that the result returned by S17DHF is accurate to less than
     half of machine precision. This error exit may occur if ABS
     (Z) is greater than a machine-dependent threshold value
     (given in the Users' Note for your implementation).

IFAIL= 4
     No computation has been performed because the errors due to
     argument reduction in elementary functions mean that all
     precision in the result returned by S17DHF would be lost.
     This error exit may occur if ABS(Z) is greater than a
     machine-dependent threshold value (given in the Users' Note
     for your implementation).

IFAIL= 5
     No result is returned because the algorithm termination
     condition has not been met. This may occur because the
     parameters supplied to S17DHF would have caused overflow or
     underflow.

7. Accuracy

All constants in subroutine S17DHF are given to approximately 18
digits of precision. Calling the number of digits of precision in
the floating-point arithmetic being used t, then clearly the
maximum number of correct digits in the results obtained is
limited by p=min(t,18). Because of errors in argument reduction
when computing elementary functions inside S17DHF, the actual
number of correct digits is limited, in general, by p-s, where
s~max(1,|log  |z||) represents the number of digits lost due to
            10
```

```
          the argument reduction. Thus the larger the value of |z|, the
          less the precision in the result.

          Empirical tests with modest values of z, checking relations
          between Airy functions Ai(z), Ai'(z), Bi(z) and Bi'(z), have
          shown errors limited to the least significant 3-4 digits of
          precision.

          8. Further Comments

          Note that if the function is required to operate on a real
          argument only, then it may be much cheaper to call S17AHF or
          S17AKF.

          9. Example

          The example program prints a caption and then proceeds to read
          sets of data from the input data stream. The first datum is a
          value for the parameter DERIV, the second is a complex value for
          the argument, Z, and the third is a value for the parameter
          SCALE. The program calls the routine and prints the results. The
          process is repeated until the end of the input data stream is
          encountered.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

16.6.23 Returns a sequence of values for the Hankel functions

— **nags.ht** —

```
\begin{page}{manpageXXs17dlf}{NAG Documentation: s17dlf}
\beginscroll
\begin{verbatim}

     S17DLF(3NAG)      Foundation Library (12/10/92)      S17DLF(3NAG)
```

```
S17 -- Approximations of Special Functions                S17DLF
        S17DLF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S17DLF returns a sequence of values for the Hankel functions
 (1)          (2)
H      (z) or H      (z) for complex z, non-negative (nu) and
 (nu)+n        (nu)+n
n=0,1,...,N-1, with an option for exponential scaling.

2. Specification

       SUBROUTINE S17DLF (M, FNU, Z, N, SCALE, CY, NZ, IFAIL)
       INTEGER             M, N, NZ, IFAIL
       DOUBLE PRECISION    FNU
       COMPLEX(KIND(1.0D0)) Z, CY(N)
       CHARACTER*1         SCALE

3. Description

This subroutine evaluates a sequence of values for the Hankel
          (1)         (2)
function H    (z) or H    (z), where z is complex, -(pi) < argz
          (nu)        (nu)
<= (pi), and (nu) is the real, non-negative order. The N-member
sequence is generated for orders (nu), (nu)+1,...,(nu)+N-1.
                                                   -iz
Optionally, the sequence is scaled by the factor e    if the
             (1)                        iz
function is H    (z) or by the factor e   if the function is
             (nu)
 (2)
H    (z).
 (nu)

Note: although the routine may not be called with (nu) less than
zero, for negative orders the formulae
 (1)       (nu)(pi)i (1)           (2)       -(nu)(pi)i (2)
H     (z)=e         H    (z), and H     (z)=e          H    (z)
 -(nu)               (nu)          -(nu)                (nu)
may be used.

The routine is derived from the routine CBESH in Amos [2]. It is
```

based on the relation

$$H^{(m)}_{(nu)}(z)= \frac{1}{p} e^{-p(nu)} K_{(nu)}(ze^{-p}),$$

where $p=i\frac{(pi)}{2}$ if m=1 and $p=-i\frac{(pi)}{2}$ if m=2, and the Bessel function $K_{(nu)}(z)$ is computed in the right half-plane only. Continuation of $K_{(nu)}(z)$ to the left half-plane is computed in terms of the Bessel function $I_{(nu)}(z)$. These functions are evaluated using a variety of different techniques, depending on the region under consideration.

When N is greater than 1, extra values of $H^{(m)}_{(nu)}(z)$ are computed using recurrence relations.

For very large |z| or ((nu)+N-1), argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller |z| or ((nu)+N-1), the computation is performed but results are accurate to less than half of machine precision. If |z| is very small, near the machine underflow threshold, or ((nu)+N-1) is too large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

4. References

[2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

5. Parameters

1: M -- INTEGER Input

On entry: the kind of functions required.

If M = 1, the functions are $H^{(1)}_{(nu)}(z)$.

(2)

```
          If M = 2, the functions are H    (z).
                                      (nu)
     Constraint: M = 1 or 2.

 2:  FNU -- DOUBLE PRECISION                              Input
     On entry: the order, (nu), of the first member of the
     sequence of functions. Constraint: FNU >= 0.0.

 3:  Z -- COMPLEX(KIND(1.0D0))                            Input
     On entry: the argument z of the functions. Constraint: Z /=
     (0.0, 0.0).

 4:  N -- INTEGER                                         Input
     On entry: the number, N, of members required in the sequence
      (M)    (M)          (M)
     H    , H      ,..., H        . Constraint: N >= 1.
      (nu)   (nu)+1       (nu)+N-1

 5:  SCALE -- CHARACTER*1                                 Input
     On entry: the scaling option.
          If SCALE = 'U', the results are returned unscaled.

          If SCALE = 'S', the results are returned scaled by the
                  -iz                               iz
          factor e    when M = 1, or by the factor e   when M =
          2.
     Constraint: SCALE = 'U' or 'S'.

 6:  CY(N) -- COMPLEX(KIND(1.0D)) array                  Output
     On exit: the N required function values: CY(i) contains
      (M)
     H        , for i=1,2,...,N.
      (nu)+i-1

 7:  NZ -- INTEGER                                       Output
     On exit: the number of components of CY that are set to zero
     due to underflow. If NZ > 0, then if Imz>0.0 and M = 1, or
     Imz<0.0 and M = 2, elements CY(1), CY(2),...,CY(NZ) are set
     to zero. In the complementary half-planes, NZ simply states
     the number of underflows, and not which elements they are.

 8:  IFAIL -- INTEGER                              Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings
```

```
Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry M /= 1 and M /= 2,

     or       FNU < 0.0,

     or       Z = (0.0, 0.0),

     or       N < 1,

     or       SCALE /= 'U' or 'S'.

IFAIL= 2
     No computation has been performed due to the likelihood of
     overflow, because ABS(Z) is less than a machine-dependent
     threshold value (given in the Users' Note for your
     implementation).

IFAIL= 3
     No computation has been performed due to the likelihood of
     overflow, because FNU + N - 1 is too large - how large
     depends on Z and the overflow threshold of the machine.

IFAIL= 4
     The computation has been performed, but the errors due to
     argument reduction in elementary functions make it likely
     that the results returned by S17DLF are accurate to less
     than half of machine precision. This error exit may occur if
     either ABS(Z) or FNU + N - 1 is greater than a machine-
     dependent threshold value (given in the Users' Note for
     your implementation).

IFAIL= 5
     No computation has been performed because the errors due to
     argument reduction in elementary functions mean that all
     precision in results returned by S17DLF would be lost. This
     error exit may occur when either of ABS(Z) or FNU + N - 1 is
     greater than a machine-dependent threshold value (given in
     the Users' Note for your implementation).

IFAIL= 6
     No results are returned because the algorithm termination
     condition has not been met. This may occur because the
     parameters supplied to S17DLF would have caused overflow or
     underflow.
```

7. Accuracy

All constants in subroutine S17DLF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used t, then clearly the maximum number of correct digits in the results obtained is limited by p=min(t,18). Because of errors in argument reduction when computing elementary functions inside S17DLF, the actual number of correct digits is limited, in general, by p-s, where s~max(1,$|\log_{10}|z||$,$|\log_{10}(nu)|$) represents the number of digits lost due to the argument reduction. Thus the larger the values of |z| and (nu), the less the precision in the result. If S17DLF is called with N>1, then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S17DLF with different base values of (nu) and different N, the computed values may not agree exactly. Empirical tests with modest values of (nu) and z have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

8. Further Comments

The time taken by the routine for a call of S17DLF is approximately proportional to the value of N, plus a constant. In general it is much cheaper to call S17DLF with N greater than 1, rather than to make N separate calls to S17DLF.

Paradoxically, for some values of z and (nu), it is cheaper to call S17DLF with a larger value of N than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different N, and the costs in each region may differ greatly.

9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the kind of function, M, the second is a value for the order FNU, the third is a complex value for the argument, Z, and the fourth is a value for the parameter SCALE. The program calls the routine with N = 2 to evaluate the function for orders FNU and FNU + 1, and it prints the results. The process is repeated until the end of the input data stream is encountered.

```
          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

\end{page}
```

———-

16.6.24 Returns the value of the modified Bessel Function $K_0(x)$

— nags.ht —

```
\begin{page}{manpageXXs18acf}{NAG Documentation: s18acf}
\beginscroll
\begin{verbatim}

     S18ACF(3NAG)      Foundation Library (12/10/92)      S18ACF(3NAG)

          S18 -- Approximations of Special Functions                S18ACF
                  S18ACF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          S18ACF returns the value of the modified Bessel Function K (x),
                                                                   0
          via the routine name.

          2. Specification

                 DOUBLE PRECISION FUNCTION S18ACF (X, IFAIL)
                 INTEGER          IFAIL
                 DOUBLE PRECISION X

          3. Description

          This routine evaluates an approximation to the modified Bessel
          Function of the second kind K (x).
```

0

Note: $K_0(x)$ is undefined for $x<=0$ and the routine will fail for such arguments.

The routine is based on five Chebyshev expansions:

For $0<x<=1$,

$$K_0(x)=-\ln x {\sum_{r=0}}' a_r T_r(t)+ {\sum_{r=0}}' b_r T_r(t) \text{ , where } t=2x^2-1;$$

For $1<x<=2$,

$$K_0(x)=e^{-x} {\sum_{r=0}}' c_r T_r(t) \text{ , where } t=2x-3;$$

For $2<x<=4$,

$$K_0(x)=e^{-x} {\sum_{r=0}}' d_r T_r(t) \text{ , where } t=x-3;$$

For $x>4$,

$$K_0(x)= \frac{e^{-x}}{\sqrt{x}} {\sum_{r=0}}' e_r T_r(t) \text{ , where } t= \frac{9-x}{1+x}.$$

For x near zero, $K_0(x)\simeq-\gamma-\ln\left(\frac{x}{2}\right)$, where γ denotes Euler's constant. This approximation is used when x is sufficiently small for the result to be correct to machine precision.

For large x, where there is a danger of underflow due to the smallness of K_0, the result is set exactly to zero.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical

Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function. Constraint: X > 0. 0.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
X <= 0.0, K_0 is undefined. On soft failure the routine returns zero.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

$$(\text{epsilon}) \simeq \left| \frac{xK_1(x)}{K_0(x)} \right| (\text{delta}).$$

Figure 1 shows the behaviour of the error amplification factor

$$\left| \frac{xK_1(x)}{K_0(x)} \right|.$$

Figure 1
Please see figure in printed Reference Manual

```
          However, if (delta) is of the same order as machine precision,
          then rounding errors could make (epsilon) slightly larger than
          the above relation predicts.

                                                                 |  1 |
          For small x, the amplification factor is approximately | ---|,
                                                                 | lnx|
          which implies strong attenuation of the error, but in general
          (epsilon) can never be less than the machine precision.

          For large x, (epsilon)~=x(delta) and we have strong amplification
          of the relative error. Eventually K , which is asymptotically
                                             0
                     -x
                    e
          given by  ---, becomes so small that it cannot be calculated

                    \/x
          without underflow and hence the routine will return zero. Note
          that for large x the errors will be dominated by those of the
          Fortran intrinsic function EXP.

          8. Further Comments

          For details of the time taken by the routine see the appropriate
          the Users' Note for your implementation.

          9. Example

          The example program reads values of the argument x from a file,
          evaluates the function at each value of x and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

     S18ADF(3NAG)      Foundation Library (12/10/92)      S18ADF(3NAG)

          S18 -- Approximations of Special Functions                S18ADF
                  S18ADF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          S18ADF returns the value of the modified Bessel Function K (x),
                                                                   1
          via the routine name.

          2. Specification

                 DOUBLE PRECISION FUNCTION S18ADF (X, IFAIL)
                 INTEGER          IFAIL
                 DOUBLE PRECISION X

          3. Description

          This routine evaluates an approximation to the modified Bessel
          Function of the second kind K (x).
                                       1

          Note: K (x) is undefined for x<=0 and the routine will fail for
                 1
          such arguments.

          The routine is based on five Chebyshev expansions:

          For 0<x<=1,

                     1      --'           --'                     2
              K (x)= -+xlnx >   a T (t)-x >   b T (t) , where t=2x -1;
               1     x      --   r r      --   r r
                            r=0           r=0

          For 1<x<=2,
```

$$K_1(x)=e^{-x}\sum_{r=0}{}' c_r T_r(t)\text{ , where } t=2x-3;$$

For 2<x<=4,

$$K_1(x)=e^{-x}\sum_{r=0}{}' d_r T_r(t)\text{ , where } t=x-3;$$

For x>4,

$$K_1(x)=\frac{e^{-x}}{\sqrt{x}}\sum_{r=0}{}' e_r T_r(t)\text{ , where } t=\frac{9-x}{1+x}.$$

For x near zero, $K_1(x)\simeq\frac{1}{x}$. This approximation is used when x is sufficiently small for the result to be correct to machine precision. For very small x on some machines, it is impossible to calculate $\frac{1}{x}$ without overflow and the routine must fail.

For large x, where there is a danger of underflow due to the smallness of K_1, the result is set exactly to zero.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function. Constraint: X > 0. 0.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
: $X <= 0.0$, K_1 is undefined. On soft failure the routine returns zero.

IFAIL= 2
: X is too small, there is a danger of overflow. On soft failure the routine returns approximately the largest representable value.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

$$(\epsilon) \simeq \left| \frac{xK_0(x)-K_1(x)}{K_1(x)} \right| (\delta).$$

Figure 1 shows the behaviour of the error amplification factor

$$\left| \frac{xK_0(x)-K_1(x)}{K_1(x)} \right|.$$

Figure 1
Please see figure in printed Reference Manual

However if (delta) is of the same order as the machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

For small x, $(\epsilon) \simeq (\delta)$ and there is no amplification of errors.

```
          For large x, (epsilon)~=x(delta) and we have strong amplification
          of the relative error. Eventually K , which is asymptotically
                                             1
                     -x
                    e
          given by  ---, becomes so small that it cannot be calculated

                    \/x
          without underflow and hence the routine will return zero. Note
          that for large x the errors will be dominated by those of the
          Fortran intrinsic function EXP.

          8. Further Comments

          For details of the time taken by the routine see the Users' Note
          for your implementation.

          9. Example

          The example program reads values of the argument x from a file,
          evaluates the function at each value of x and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

S18 -- Approximations of Special Functions S18AEF

S18AEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S18AEF returns the value of the modified Bessel Function $I_0(x)$, via the routine name.

2. Specification

```
       DOUBLE PRECISION FUNCTION S18AEF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the modified Bessel Function of the first kind $I_0(x)$.

Note: $I_0(-x)=I_0(x)$, so the approximation need only consider $x>=0$.

The routine is based on three Chebyshev expansions:

For $0<x<=4$,

$$I_0(x)=e^x \sum_{r=0}' a_r T_r(t) \text{ , where } t=2\left(\frac{x}{4}\right)-1;$$

For $4<x<=12$,

$$I_0(x)=e^x \sum_{r=0}' b_r T_r(t) \text{ , where } t=\frac{x-8}{4};$$

For $x>12$,

```
             x
            e   --'                        ( 12)
     I (x)= --- >   c T (t) , where t=2( --)-1.
```

```
            0         --   r r              ( x )
                  \/x r=0
```

```
For small x, I (x)~=1. This approximation is used when x is
              0
sufficiently small for the result to be correct to machine
precision.
```

```
For large x, the routine must fail because of the danger of
                         x
overflow in calculating e  .
```

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

```
 1:  X -- DOUBLE PRECISION                                  Input
     On entry: the argument x of the function.

 2:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).
```

6. Error Indicators and Warnings

Errors detected by the routine:

```
IFAIL= 1
     X is too large. On soft failure the routine returns the
     approximate value of I (x) at the nearest valid argument.
                           0
```

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

```
                               | xI (x)|
                               |   1   |
                          (epsilon)~=| ------|(delta).
                                     | I (x) |
                                     |  0    |

          Figure 1 shows the behaviour of the error amplification factor

                                    | xI (x)|
                                    |   1   |
                                    | ------|.
                                    | I (x) |
                                    |  0    |

                                    Figure 1
                   Please see figure in printed Reference Manual

          However if (delta) is of the same order as machine precision,
          then rounding errors could make (epsilon) slightly larger than
          the above relation predicts.

                                                                 2
                                                                x
          For small x the amplification factor is approximately  --, which
                                                                2
          implies strong attenuation of the error, but in general (epsilon)
          can never be less than the machine precision.

          For large x, (epsilon)~=x(delta) and we have strong amplification
          of errors. However the routine must fail for quite moderate
          values of x, because I (x) would overflow; hence in practice the
                                0
          loss of accuracy for large x is not excessive. Note that for
          large x the errors will be dominated by those of the Fortran
          intrinsic function EXP.

          8. Further Comments

          For details of the time taken by the routine see the Users' Note
          for your implementation.

          9. Example

          The example program reads values of the argument x from a file,
          evaluates the function at each value of x and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          S18AFF returns a value for the modified Bessel Function I (x),
                                                                   1
          via the routine name.

          2. Specification

                 DOUBLE PRECISION FUNCTION S18AFF (X, IFAIL)
                 INTEGER          IFAIL
                 DOUBLE PRECISION X

          3. Description

          This routine evaluates an approximation to the modified Bessel
          Function of the first kind I (x).
                                      1

          Note: I (-x)=-I (x), so the approximation need only consider x>=0
                 1       1

          The routine is based on three Chebyshev expansions:
```

For $0<x\le 4$,

$$I_1(x)=x\sum_{r=0}{}' a_r T_r(t), \text{ where } t=2\left(\frac{x}{4}\right)^2-1;$$

For $4<x\le 12$,

$$I_1(x)=e^x\sum_{r=0}{}' b_r T_r(t), \text{ where } t=\frac{x-8}{4};$$

For $x>12$,

$$I_1(x)=\frac{e^x}{\sqrt{x}}\sum_{r=0}{}' c_r T_r(t), \text{ where } t=2\left(\frac{12}{x}\right)-1.$$

For small x, $I_1(x)\simeq x$. This approximation is used when x is sufficiently small for the result to be correct to machine precision.

For large x, the routine must fail because $I_1(x)$ cannot be represented without overflow.

     S18DCF(3NAG)      Foundation Library (12/10/92)      S18DCF(3NAG)

          S18 -- Approximations of Special Functions                 S18DCF
                  S18DCF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          S18DCF returns a sequence of values for the modified Bessel
          functions K      (z) for complex z, non-negative (nu) and
                     (nu)+n
          n=0,1,...,N-1, with an option for exponential scaling.
```

2. Specification

```
      SUBROUTINE S18DCF (FNU, Z, N, SCALE, CY, NZ, IFAIL)
      INTEGER              N, NZ, IFAIL
      DOUBLE PRECISION     FNU
      COMPLEX(KIND(1.0D0)) Z, CY(N)
      CHARACTER*1          SCALE
```

3. Description

This subroutine evaluates a sequence of values for the modified Bessel function $K_{(nu)}(z)$, where z is complex, -(pi) < arg z <= (pi), and (nu) is the real, non-negative order. The N-member sequence is generated for orders (nu), (nu)+1,...,(nu)+N-1. Optionally, the sequence is scaled by the factor e^{z}.

The routine is derived from the routine CBESK in Amos [2].

Note: although the routine may not be called with (nu) less than zero, for negative orders the formula $K_{-(nu)}(z)=K_{(nu)}(z)$ may be used.

When N is greater than 1, extra values of $K_{(nu)}(z)$ are computed using recurrence relations.

For very large |z| or ((nu)+N-1), argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller |z| or ((nu)+N-1), the computation is performed but results are accurate to less than half of machine precision. If |z| is very small, near the machine underflow threshold, or ((nu)+N-1) is too large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

[2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

5. Parameters

1: FNU -- DOUBLE PRECISION Input
On entry: the order, (nu), of the first member of the sequence of functions. Constraint: FNU >= 0.0.

2: Z -- COMPLEX(KIND(1.0D0)) Input
On entry: the argument z of the functions. Constraint: Z /= (0.0, 0.0).

3: N -- INTEGER Input
On entry: the number, N, of members required in the sequence $K_{(nu)}(z)$, $K_{(nu)+1}(z)$,..., $K_{(nu)+N-1}(z)$. Constraint: N >= 1.

4: SCALE -- CHARACTER*1 Input
On entry: the scaling option.

If SCALE = 'U', the results are returned unscaled.

If SCALE = 'S', the results are returned scaled by the factor e^{z}. Constraint: SCALE = 'U' or 'S'.

5: CY(N) -- COMPLEX(KIND(1.0D)) array Output
On exit: the N required function values: CY(i) contains $K_{(nu)+i-1}(z)$, for i=1,2,...,N.

6: NZ -- INTEGER Output
On exit: the number of components of CY that are set to zero due to underflow. If NZ > 0 and Rez>=0.0, elements CY(1),CY(2),...,CY(NZ) are set to zero. If Rez<0.0, NZ simply states the number of underflows, and not which elements they are.

7: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

```
     On entry FNU < 0.0,

     or       Z = (0.0, 0.0),

     or       N < 1,

     or       SCALE /= 'U' or 'S'.

IFAIL= 2
     No computation has been performed due to the likelihood of
     overflow, because ABS(Z) is less than a machine-dependent
     threshold value (given in the Users' Note for your
     implementation).

IFAIL= 3
     No computation has been performed due to the likelihood of
     overflow, because FNU + N - 1 is too large - how large
     depends on Z and the overflow threshold of the machine.

IFAIL= 4
     The computation has been performed, but the errors due to
     argument reduction in elementary functions make it likely
     that the results returned by S18DCF are accurate to less
     than half of machine precision. This error exit may occur if
     either ABS(Z) or FNU + N - 1 is greater than a machine-
     dependent threshold value (given in the Users' Note for
     your implementation).

IFAIL= 5
     No computation has been performed because the errors due to
     argument reduction in elementary functions mean that all
     precision in results returned by S18DCF would be lost. This
     error exit may occur when either ABS(Z) or FNU + N - 1 is
     greater than a machine-dependent threshold value (given in
     the Users' Note for your implementation).

IFAIL= 6
     No results are returned because the algorithm termination
     condition has not been met. This may occur because the
     parameters supplied to S18DCF would have caused overflow or
     underflow.

7. Accuracy

All constants in subroutine S18DCF are given to approximately 18
digits of precision. Calling the number of digits of precision in
the floating-point arithmetic being used t, then clearly the
maximum number of correct digits in the results obtained is
limited by p=min(t,18). Because of errors in argument reduction
```

when computing elementary functions inside S18DCF, the actual number of correct digits is limited, in general, by p-s, where $s \sim max(1,|\log_{10}|z||,|\log_{10}(nu)|)$ represents the number of digits lost due to the argument reduction. Thus the larger the values of |z| and (nu), the less the precision in the result. If S18DCF is called with N>1, then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S18DCF with different base values of (nu) and different N, the computed values may not agree exactly. Empirical tests with modest values of (nu) and z have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

8. Further Comments

The time taken by the routine for a call of S18DCF is approximately proportional to the value of N, plus a constant. In general it is much cheaper to call S18DCF with N greater than 1, rather than to make N separate calls to S18DCF.

Paradoxically, for some values of z and (nu), it is cheaper to call S18DCF with a larger value of N than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different N, and the costs in each region may differ greatly.

Note that if the function required is $K_0(x)$ or $K_1(x)$, i.e., (nu)=0.0 or 1.0, where x is real and positive, and only a single function value is required, then it may be much cheaper to call S18ACF, S18ADF, S18CCF(*) or S18CDF(*), depending on whether a scaled result is required or not.

9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the order FNU, the second is a complex value for the argument, Z, and the third is a value for the parameter SCALE. The program calls the routine with N = 2 to evaluate the function for orders FNU and FNU + 1, and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for

     S18DEF(3NAG)      Foundation Library (12/10/92)      S18DEF(3NAG)

         S18 -- Approximations of Special Functions                 S18DEF
                 S18DEF -- NAG Foundation Library Routine Document

         Note: Before using this routine, please read the Users' Note for
         your implementation to check implementation-dependent details.
         The symbol (*) after a NAG routine name denotes a routine that is
         not included in the Foundation Library.

         1. Purpose

         S18DEF returns a sequence of values for the modified Bessel
         functions I      (z) for complex z, non-negative (nu) and
                    (nu)+n
         n=0,1,...,N-1, with an option for exponential scaling.

         2. Specification

                SUBROUTINE S18DEF (FNU, Z, N, SCALE, CY, NZ, IFAIL)
                INTEGER              N, NZ, IFAIL
                DOUBLE PRECISION     FNU
                COMPLEX(KIND(1.0D0)) Z, CY(N)
                CHARACTER*1          SCALE

         3. Description
```

This subroutine evaluates a sequence of values for the modified Bessel function $I_{(nu)}(z)$, where z is complex, -(pi) < argz <= (pi), and (nu) is the real, non-negative order. The N-member sequence is generated for orders (nu), (nu)+1,...,(nu)+N-1. Optionally, the sequence is scaled by the factor $e^{-|Rez|}$.

The routine is derived from the routine CBESI in Amos [2].

Note: although the routine may not be called with (nu) less than zero, for negative orders the formula $I_{-(nu)}(z)=I_{(nu)}(z)+\frac{2}{(pi)}sin((pi)(nu))K_{(nu)}(z)$ may be used (for the Bessel function $K_{(nu)}(z)$, see S18DCF).

When N is greater than 1, extra values of $I_{(nu)}(z)$ are computed using recurrence relations.

For very large |z| or ((nu)+N-1), argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller |z| or ((nu)+N-1), the computation is performed but results are accurate to less than half of machine precision. If Re(z) is too large and the unscaled function is required, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

[2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

5. Parameters

1: FNU -- DOUBLE PRECISION Input
On entry: the order, (nu), of the first member of the sequence of functions. Constraint: FNU >= 0.0.

2: Z -- COMPLEX(KIND(1.0D0)) Input
On entry: the argument z of the functions.

3: N -- INTEGER Input

```
     On entry: the number, N, of members required in the sequence
     I    (z),I      (z),...,I        (z). Constraint: N >= 1.
      (nu)     (nu)+1         (nu)+N-1

 4:  SCALE -- CHARACTER*1                                  Input
     On entry: the scaling option.
          If SCALE = 'U', the results are returned unscaled.

          If SCALE = 'S', the results are returned scaled by the
                 -|Rez|
          factor e      .
     Constraint: SCALE = 'U' or 'S'.

 5:  CY(N) -- COMPLEX(KIND(1.0D)) array                   Output
     On exit: the N required function values: CY(i) contains
     I       (z), for i=1,2,...,N.
      (nu)+i-1

 6:  NZ -- INTEGER                                        Output
     On exit: the number of components of CY that are set to zero
     due to underflow.

     If NZ > 0, then elements CY(N-NZ+1),CY(N-NZ+2),...,CY(N) are
     set to zero.

 7:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry FNU < 0.0,

     or       N < 1,

     or       SCALE /= 'U' or 'S'.

IFAIL= 2
     No computation has been performed due to the likelihood of
     overflow, because real(Z) is greater than a machine-
     dependent threshold value (given in the Users' Note for
     your implementation). This error exit can only occur when
     SCALE = 'U'.

IFAIL= 3
     The computation has been performed, but the errors due to
     argument reduction in elementary functions make it likely
     that the results returned by S18DEF are accurate to less
     than half of machine precision. This error exit may occur
     when either ABS(Z) or FNU + N - 1 is greater than a machine-
     dependent threshold value (given in the Users' Note for
     your implementation).

IFAIL= 4
     No computation has been performed because the errors due to
     argument reduction in elementary functions mean that all
     precision in results returned by S18DEF would be lost. This
     error exit may occur when either ABS(Z) or FNU + N - 1 is
     greater than a machine-dependent threshold value (given in
     the Users' Note for your implementation).

IFAIL= 5
     No results are returned because the algorithm termination
     condition has not been met. This may occur because the
     parameters supplied to S18DEF would have caused overflow or
     underflow.

7. Accuracy

All constants in subroutine S18DEF are given to approximately 18
digits of precision. Calling the number of digits of precision in
the floating-point arithmetic being used t, then clearly the
maximum number of correct digits in the results obtained is
limited by p=min(t,18). Because of errors in argument reduction
when computing elementary functions inside S18DEF, the actual
number of correct digits is limited, in general, by p-s, where
s~max(1,|log  |z||,|log  (nu)|) represents the number of digits
            10         10
lost due to the argument reduction. Thus the larger the values of
|z| and (nu), the less the precision in the result. If S18DEF is
called with N>1, then computation of function values via
recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are
computed by calls to S18DEF with different base values of (nu)
and different N, the computed values may not agree exactly.
Empirical tests with modest values of (nu) and z have shown that
the discrepancy is limited to the least significant 3-4 digits of
precision.
```

```
          8. Further Comments

          The time taken by the routine for a call of S18DEF is
          approximately proportional to the value of N, plus a constant. In
          general it is much cheaper to call S18DEF with N greater than 1,
          rather than to make N separate calls to S18DEF.

          Paradoxically, for some values of z and (nu), it is cheaper to
          call S18DEF with a larger value of N than is required, and then
          discard the extra function values returned. However, it is not
          possible to state the precise circumstances in which this is
          likely to occur. It is due to the fact that the base value used
          to start recurrence may be calculated in different regions for
          different N, and the costs in each region may differ greatly.

          Note that if the function required is I (x) or I (x), i.e.,
                                                 0        1
          (nu)=0.0 or 1.0, where x is real and positive, and only a single
          function value is required, then it may be much cheaper to call
          S18AEF, S18AFF, S18CEF(*) or S18CFF(*), depending on whether a
          scaled result is required or not.

          9. Example

          The example program prints a caption and then proceeds to read
          sets of data from the input data stream. The first datum is a
          value for the order FNU, the second is a complex value for the
          argument, Z, and the third is a value for the parameter SCALE.
          The program calls the routine with N = 2 to evaluate the function
          for orders FNU and FNU + 1, and it prints the results. The
          process is repeated until the end of the input data stream is
          encountered.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

                  S19AAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          S19AAF returns a value for the Kelvin function ber x via the
          routine name.

          2. Specification

                 DOUBLE PRECISION FUNCTION S19AAF (X, IFAIL)
                 INTEGER          IFAIL
                 DOUBLE PRECISION X

          3. Description

          This routine evaluates an approximation to the Kelvin function
          berx.

          Note: ber(-x)=berx, so the approximation need only consider
          x>=0.0.

          The routine is based on several Chebyshev expansions:

          For 0<=x<=5,

                               --'                 ( x)4
                          berx= >   a T (t) with t=2( -) -1;
                               --   r r            ( 5)
                               r=0

          For x>5,
                        x/\/2
                       e      [(   1    )           1             ]
                berx= --------[(1+ -a(t))cos(alpha)+ -b(t)sin(alpha)]
                              [(   x    )           x             ]
                      \/2(pi)x

                       -x/\/2
                      e      [(   1    )           1             ]
                   + --------[(1+ -c(t))sin(beta)+ -d(t)cos(beta)]
                             [(   x    )           x             ]
                     \/2(pi)x

                          x   (pi)           x   (pi)
          where (alpha)= ---- ----, (beta)= ---+ ----,
                               8                  8
                         \/2               /2
```

```
and a(t), b(t), c(t), and d(t) are expansions in the variable
   10
t= ---1.
   x
```

When x is sufficiently close to zero, the result is set directly to ber 0=1.0.

For large x, there is a danger of the result being totally inaccurate, as the error amplification factor grows in an essentially exponential manner; therefore the routine must fail.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     On entry ABS(X) is too large for an accurate result to be
     returned. On soft failure, the routine returns zero.

7. Accuracy

Since the function is oscillatory, the absolute error rather than the relative error is important. Let E be the absolute error in the result and (delta) be the relative error in the argument. If (delta) is somewhat larger than the machine precision, then we have:

$$E \simeq \left| \frac{x}{\sqrt{2}}(\mathrm{ber}_1 x + \mathrm{bei}_1 x) \right| (\delta)$$

(provided E is within machine bounds).

For small x the error amplification is insignificant and thus the absolute error is effectively bounded by the machine precision.

For medium and large x, the error behaviour is oscillatory and

its amplitude grows like $\sqrt{\frac{x}{2(\pi)}}e^{x/\sqrt{2}}$. Therefore it is not

possible to calculate the function with any accuracy when

$\sqrt{x}e^{x/\sqrt{2}} > \frac{\sqrt{2(\pi)}}{(\delta)}$. Note that this value of x is much smaller than

the minimum value of x for which the function overflows.

8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

```
         The example program is not reproduced here. The source code for
         all example programs is distributed with the NAG Foundation
         Library software and should be available on-line.

     S19ABF(3NAG)      Foundation Library (12/10/92)      S19ABF(3NAG)

         S19 -- Approximations of Special Functions                S19ABF
                 S19ABF -- NAG Foundation Library Routine Document

         Note: Before using this routine, please read the Users' Note for
         your implementation to check implementation-dependent details.
         The symbol (*) after a NAG routine name denotes a routine that is
         not included in the Foundation Library.

         1. Purpose

         S19ABF returns a value for the Kelvin function bei x via the
         routine name.

         2. Specification

                DOUBLE PRECISION FUNCTION S19ABF (X, IFAIL)
                INTEGER          IFAIL
                DOUBLE PRECISION X

         3. Description

         This routine evaluates an approximation to the Kelvin function
         beix.
```

Note: bei(-x)=beix, so the approximation need only consider x>=0.0.

The routine is based on several Chebyshev expansions:

For 0<=x<=5,

$$\mathrm{bei}\ x=\frac{x^2}{4}\sum_{r=0}{}' a_r T_r(t),\quad \text{with}\quad t=2\left(\frac{x}{5}\right)^4-1;$$

For x>5,

$$\mathrm{bei}\ x=\frac{e^{x/\sqrt{2}}}{\sqrt{2(\pi)x}}\left[\left(1+\frac{1}{x}a(t)\right)\sin(\alpha)-\frac{1}{x}b(t)\cos(\alpha)\right]$$

$$+\frac{e^{x/\sqrt{2}}}{\sqrt{2(\pi)x}}\left[\left(1+\frac{1}{x}c(t)\right)\cos(\beta)-\frac{1}{x}d(t)\sin(\beta)\right]$$

where$(\alpha)=\frac{x}{\sqrt{2}}\ \frac{(\pi)}{8}$,$(\beta)=\frac{x}{/2}+\frac{(\pi)}{8}$,

and a(t), b(t), c(t), and d(t) are expansions in the variable $t=\frac{10}{x}-1$.

When x is sufficiently close to zero, the result is computed as $\mathrm{bei}\ x=\frac{x^2}{4}$. If this result would underflow, the result returned is beix=0.0.

For large x, there is a danger of the result being totally inaccurate, as the error amplification factor grows in an essentially exponential manner; therefore the routine must fail.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

```
 1:  X -- DOUBLE PRECISION                                 Input
     On entry: the argument x of the function.

 2:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).
```

6. Error Indicators and Warnings

Errors detected by the routine:

```
IFAIL= 1
     On entry ABS(X) is too large for an accurate result to be
     returned. On soft failure, the routine returns zero.
```

7. Accuracy

Since the function is oscillatory, the absolute error rather than the relative error is important. Let E be the absolute error in the function, and (delta) be the relative error in the argument. If (delta) is somewhat larger than the machine precision, then we have:

```
                |  x              |
             E~=| ---(-ber x+bei x)|(delta)
                |        1     1  |
                | \/2             |
```

(provided E is within machine bounds).

For small x the error amplification is insignificant and thus the absolute error is effectively bounded by the machine precision.

For medium and large x, the error behaviour is oscillatory and

```
                                   /   x   x\/2
          its amplitude grows like   /  -----e    . Therefore it is
                                 \/   2(pi)

          impossible to calculate the functions with any accuracy when

              x/\/2 /2(pi)
          \/xe     > -------. Note that this value of x is much smaller than
                     (delta)

          the minimum value of x for which the function overflows.

          8. Further Comments

          For details of the time taken by the routine see the Users' Note
          for your implementation.

          9. Example

          The example program reads values of the argument x from a file,
          evaluates the function at each value of x and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation

```

```
        S19ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S19ACF returns a value for the Kelvin function ker x, via the
routine name.

2. Specification

       DOUBLE PRECISION FUNCTION S19ACF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to the Kelvin function
ker x.

Note: for x<0 the function is undefined and at x=0 it is infinite
so we need only consider x>0.

The routine is based on several Chebyshev expansions:

For 0<x<=1,

                             (pi) 2
                ker x=-f(t)logx+ ----x g(t)+y(t)
                              16

                                                               4
where f(t), g(t) and y(t) are expansions in the variable t=2x -1;

For 1<x<=3,

                              (  11 )
                      ker x=exp(- --x)q(t)
                              (  16 )

where q(t) is an expansion in the variable t=x-2;

For x>3,

                  -x/\/2
```

$$\operatorname{ker} x=\sqrt{\frac{\pi}{2x}}e\left[\left(1+\frac{1}{x}c(t)\right)\cos\beta-\frac{1}{x}d(t)\sin\beta\right]$$

where $\beta=\frac{x}{\sqrt{2}}+\frac{\pi}{8}$, and $c(t)$ and $d(t)$ are expansions in the variable $t=\frac{6}{x}-1$.

When x is sufficiently close to zero, the result is computed as

$$\operatorname{ker} x=-\gamma-\log\left(\frac{x}{2}\right)+\left(\pi-\frac{3}{8}x^2\right)\frac{x^2}{16}$$

and when x is even closer to zero, simply as

$$\operatorname{ker} x=-\gamma-\log\left(\frac{x}{2}\right).$$

For large x, ker x is asymptotically given by $\sqrt{\frac{\pi}{2x}}e^{-x/\sqrt{2}}$ and this becomes so small that it cannot be computed without underflow and the routine fails.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function. Constraint: X > 0.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see

```
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     On entry X is too large, the result underflows. On soft
     failure, the routine returns zero.

IFAIL= 2
     On entry X <= 0, the function is undefined. On soft failure
     the routine returns zero.

7. Accuracy

Let E be the absolute error in the result, (epsilon) be the
relative error in the result and (delta) be the relative error in
the argument. If (delta) is somewhat larger than the machine
precision, then we have:

                    |  x              |
                 E~=| ---(ker  x+kei x)|(delta),
                    |        1     1  |
                    | \/2             |

                        |     ker  x+kei x|
                        |  x      1     1 |
             (epsilon)~=| --- ------------|(delta).
                        |        ker x    |
                        | \/2             |

For very small x, the relative error amplification factor is
                          1
approximately given by  ------, which implies a strong
                        |logx|
attenuation of relative error. However, (epsilon) in general
cannot be less than the machine precision.

For small x, errors are damped by the function and hence are
limited by the machine precision.

For medium and large x, the error behaviour, like the function
itself, is oscillatory, and hence only the absolute accuracy for
the function can be maintained. For this range of x, the

                                             / (pi)x -x/\/2
amplitude of the absolute error decays like   /  -----e
                                            \/     2
```

```
          which implies a strong attenuation of error. Eventually, ker x,

                                               / (pi) -x/\/2
          which asymptotically behaves like   /  ----e      , becomes so
                                            \/    2x

          small that it cannot be calculated without causing underflow, and
          the routine returns zero. Note that for large x the errors are
          dominated by those of the Fortran intrinsic function EXP.

          8. Further Comments

          Underflow may occur for a few values of x close to the zeros of
          ker x, below the limit which causes a failure with IFAIL = 1.

          9. Example

          The example program reads values of the argument x from a file,
          evaluates the function at each value of x and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

\beginscroll
\begin{verbatim}

     S19ADF(3NAG)      Foundation Library (12/10/92)      S19ADF(3NAG)

          S19 -- Approximations of Special Functions                 S19ADF
                  S19ADF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S19ADF returns a value for the Kelvin function keix via the routine name.

2. Specification

```
       DOUBLE PRECISION FUNCTION S19ADF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Kelvin function keix.

Note: for $x<0$ the function is undefined, so we need only consider $x>=0$.

The routine is based on several Chebyshev expansions:

For $0<=x<=1$,

$$\mathrm{kei}\,x=-\frac{\pi}{4}f(t)+\frac{x^2}{4}[-g(t)\log x+v(t)]$$

where $f(t)$, $g(t)$ and $v(t)$ are expansions in the variable $t=2x^4-1$;

For $1<x<=3$,

$$\mathrm{kei}\,x=\exp\left(-\frac{9}{8}x\right)u(t)$$

where $u(t)$ is an expansion in the variable $t=x-2$;

For $x>3$,

```
            / (pi) -x/\/2[(   1)              1             ]
```

```
    keix=  /  ----e      [(1+ -)c(t)sin(beta)+ -d(t)cos(beta)]
         \/    2x        [(   x)               x             ]
```

where $\beta = \frac{x}{\sqrt{2}} + \frac{\pi}{8}$, and c(t) and d(t) are expansions in the variable $t = \frac{6}{x} - 1$.

For x<0, the function is undefined, and hence the routine fails and returns zero.

When x is sufficiently close to zero, the result is computed as

$$keix = -\frac{\pi}{4} + \left(1 - \gamma - \log\left(\frac{x}{2}\right)\right)\frac{x^2}{4}$$

and when x is even closer to zero simply as

$$keix = -\frac{\pi}{4}.$$

For large x, keix is asymptotically given by $\sqrt{\frac{\pi}{2x}}e^{-x/\sqrt{2}}$ and this becomes so small that it cannot be computed without underflow and the routine fails.

4. References

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function. Constraint: X >= 0.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not

familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
On entry X is too large, the result underflows. On soft failure, the routine returns zero.

IFAIL= 2
On entry X < 0, the function is undefined. On soft failure the routine returns zero.

7. Accuracy

Let E be the absolute error in the result, and (delta) be the relative error in the argument. If (delta) is somewhat larger than the machine representation error, then we have:

```
                |  x              |
            E~=| ---(-ker  x+kei x)|(delta).
                |         1     1  |
                | \/2              |
```

For small x, errors are attenuated by the function and hence are limited by the machine precision.

For medium and large x, the error behaviour, like the function itself, is oscillatory and hence only absolute accuracy of the function can be maintained. For this range of x, the amplitude of

```
                                 / (pi)x -x/\/2
the absolute error decays like  /  -----e       , which implies a
                              \/     2
```

strong attenuation of error. Eventually, keix, which is

```
                          / (pi) -x/\/2
asymptotically given by  /  ----e       , becomes so small that it
                       \/    2x
```

cannot be calculated without causing underflow and therefore the routine returns zero. Note that for large x, the errors are

```
          dominated by those of the Fortran intrinsic function EXP.

          8. Further Comments

          Underflow may occur for a few values of x close to the zeros of
          keix, below the limit which causes a failure with IFAIL = 1.

          9. Example

          The example program reads values of the argument x from a file,
          evaluates the function at each value of x and prints the results.

          The example program is not reproduced here. The source code for

          routine name.
```

2. Specification

```
      DOUBLE PRECISION FUNCTION S20ACF (X, IFAIL)
      INTEGER          IFAIL
      DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Fresnel Integral

$$S(x)=\int_0^x \sin\left(\frac{\pi}{2}t^2\right)dt.$$

Note: $S(x)=-S(-x)$, so the approximation need only consider $x>=0.0$

The routine is based on three Chebyshev expansions:

For $0<x<=3$,

$$S(x)=x^3 \sum_{r=0}{}' a_r T_r(t) \text{ , with } t=2\left(\frac{x}{3}\right)^4 -1;$$

For $x>3$,

$$S(x)=\frac{1}{2}-\frac{f(x)}{x}\cos\left(\frac{\pi}{2}x^2\right)-\frac{g(x)}{x^3}\sin\left(\frac{\pi}{2}x^2\right),$$

$$\text{where } f(x) = \sum_{r=0}{}' b_r T_r(t),$$

$$\text{and } g(x) = \sum_{r=0}{}' c_r T_r(t), \text{ with } t=2\left(\frac{3}{x}\right)^4 -1.$$

For small x, $S(x)\simeq\frac{\pi}{6}x^3$. This approximation is used when x is sufficiently small for the result to be correct to machine precision. For very small x, this approximation would underflow;

the result is then set exactly to zero.

For large x, $f(x)\simeq\frac{1}{\pi}$ and $g(x)\simeq\frac{1}{\pi^2}$. Therefore for moderately large x, when $\frac{1}{\pi^2 x^3}$ is negligible compared with $\frac{1}{2}$, the second term in the approximation for $x>3$ may be dropped. For very large x, when $\frac{1}{\pi x}$ becomes negligible, $S(x)\simeq\frac{1}{2}$. However there will be considerable difficulties in calculating $\cos\left(\frac{\pi}{2}x^2\right)$ accurately before this final limiting value can be used. Since $\cos\left(\frac{\pi}{2}x^2\right)$ is periodic, its value is essentially determined by the fractional part of x^2. If $x^2=N+\theta$ where N is an integer and $0\le\theta<1$, then $\cos\left(\frac{\pi}{2}x^2\right)$ depends on θ and on N modulo 4. By exploiting this fact, it is possible to retain significance in the calculation of $\cos\left(\frac{\pi}{2}x^2\right)$ either all the way to the very large x limit, or at least until the integer part of $\frac{x}{2}$ is equal to the maximum integer allowed on the machine.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

```
     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL
has been included for consistency with other routines in this
chapter.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument
and result respectively.

If (delta) is somewhat larger than the machine precision (i.e.,
if (delta) is due to data errors etc), then (epsilon) and (delta)
are approximately related by:

                          |     ( (pi) 2)|
                          | xsin( ----x )|
                          |     (  2    )|
               (epsilon)~=| -------------|(delta).
                          |     S(x)     |

Figure 1 shows the behaviour of the error amplification factor

|     ( (pi) 2)|
| xsin( ----x )|
|     (  2    )|
| -------------|.
|     S(x)     |

                           Figure 1
         Please see figure in printed Reference Manual

However if (delta) is of the same order as the machine precision,
then rounding errors could make (epsilon) slightly larger than
the above relation predicts.

For small x, (epsilon)~=3(delta) and hence there is only moderate
amplification of relative error. Of course for very small x where
the correct result would underflow and exact zero is returned,
relative error-control is lost.

For moderately large values of x,

                          |     ( (pi) 2)|
              |(epsilon)|~=|2xsin( ----x )||(delta)|
                                   |     (  2    )|

          and the result will be subject to increasingly large
          amplification of errors. However the above relation breaks down
                                            1
          for large values of x (i.e., when  -- is of the order of the
                                             2
                                            x
          machine precision in this region the relative error in the result
                                      2
          is essentially bounded by  -----).
                                     (pi)x

          Hence the effects of error amplification are limited and at worst
          the relative error loss should not exceed half the possible
          number of significant figures.

          8. Further Comments

          None.

          9. Example

          The example program reads values of the argument x from a file,
          evaluates the function at each value of x and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

S20ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S20ADF returns a value for the Fresnel Integral C(x), via the routine name.

2. Specification

```
       DOUBLE PRECISION FUNCTION S20ADF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Fresnel Integral

$$C(x)=\int_0^x \cos\left(\frac{\pi}{2}t^2\right)dt.$$

Note: $C(x)=-C(-x)$, so the approximation need only consider $x>=0.0$

The routine is based on three Chebyshev expansions:

For $0<x<=3$,

$$C(x)=x\sum_{r=0}{}' a_r T_r(t) \text{ , with } t=2\left(\frac{x}{3}\right)^4-1;$$

For $x>3$,

$$C(x)=\frac{1}{2}+\frac{f(x)}{x}\sin\left(\frac{\pi}{2}x^2\right)-\frac{g(x)}{x^3}\cos\left(\frac{\pi}{2}x^2\right),$$

where $f(x) = {\sum_{r=0}}' b_r T_r(t)$,

and $g(x) = {\sum_{r=0}}' c_r T_r(t)$, with $t=2\left(\frac{3}{x}\right)^4 -1$.

For small x, $C(x) \simeq x$. This approximation is used when x is sufficiently small for the result to be correct to machine precision.

For large x, $f(x) \simeq \frac{1}{\pi}$ and $g(x) \simeq \frac{1}{\pi^2}$. Therefore for moderately large x, when $\frac{1}{\pi^2 x^3}$ is negligible compared with $\frac{1}{2}$, the second term in the approximation for $x>3$ may be dropped. For very large x, when $\frac{1}{\pi x}$ becomes negligible, $C(x) \simeq \frac{1}{2}$. However there will be considerable difficulties in calculating $\sin\left(\frac{\pi}{2} x^2\right)$ accurately before this final limiting value can be used. Since $\sin\left(\frac{\pi}{2} x^2\right)$ is periodic, its value is essentially determined by the fractional part of x^2. If $x^2 = N+\theta$, where N is an integer and $0 \le \theta < 1$, then $\sin\left(\frac{\pi}{2} x^2\right)$ depends on θ and on N modulo 4. By exploiting this fact, it is possible to retain some significance in the calculation of $\sin\left(\frac{\pi}{2} x^2\right)$ either all the way to the very large x limit, or at least until the integer part of $\frac{x}{2}$ is equal to the maximum integer allowed on the machine.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL has been included for consistency with other routines in this chapter.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

$$\epsilon \simeq \left| \frac{x\cos\left(\frac{\pi}{2}x^2\right)}{C(x)} \right| \delta .$$

Figure 1 shows the behaviour of the error amplification factor

$$\left| \frac{x\cos\left(\frac{\pi}{2}x^2\right)}{C(x)} \right| .$$

Figure 1
Please see figure in printed Reference Manual

However if (delta) is of the same order as the machine precision,

```
          then rounding errors could make (epsilon) slightly larger than
          the above relation predicts.

          For small x, (epsilon)~=(delta) and there is no amplification of
          relative error.

          For moderately large values of x,

                                   |      ( (pi) 2)|
                       |(epsilon)|~=|2xcos( ----x )||(delta)|
                                   |      (  2    )|

          and the result will be subject to increasingly large
          amplification of errors. However the above relation breaks down
                                             1
          for large values of x (i.e., when  -- is of the order of the
                                              2
                                             x
          machine precision); in this region the relative error in the
                                              2
          result is essentially bounded by  -----).
                                            (pi)x

          Hence the effects of error amplification are limited and at worst
          the relative error loss should not exceed half the possible
          number of significant figures.

          8. Further Comments

          None.

          9. Example

          The example program reads values of the argument x from a file,
          evaluates the function at each value of x and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

     S21BAF(3NAG)      Foundation Library (12/10/92)      S21BAF(3NAG)

          S21 -- Approximations of Special Functions                S21BAF
                  S21BAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          S21BAF returns a value of an elementary integral, which occurs as
          a degenerate case of an elliptic integral of the first kind, via
          the routine name.

          2. Specification

                 DOUBLE PRECISION FUNCTION S21BAF (X, Y, IFAIL)
                 INTEGER          IFAIL
                 DOUBLE PRECISION X, Y

          3. Description

          This routine calculates an approximate value for the integral

                                       infty
                                     1 /        dt
                          R (x,y)= - |     ----------
                           C       2 /
                                       0     \/t+x(t+y)

          where x>=0 and y/=0.

          This function, which is related to the logarithm or inverse
          hyperbolic functions for y<x and to inverse circular functions if
          x<y, arises as a degenerate form of the elliptic integral of the
```

first kind. If $y<0$, the result computed is the Cauchy principal value of the integral.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the system:

$$x_0 = x,$$

$$y_0 = y$$

$$\mu_n = (x_n + 2y_n)/3,$$

$$S_n = (y_n - x_n)/3\mu_n$$

$$\lambda_n = y_n + 2\sqrt{x_n y_n}$$

$$x_{n+1} = (x_n + \lambda_n)/4,$$

$$y_{n+1} = (y_n + \lambda_n)/4.$$

The quantity $|S_n|$ for $n=0,1,2,3,\ldots$ decreases with increasing n, eventually $|S_n| \sim 1/4^n$. For small enough S_n the required function value can be approximated by the first few terms of the Taylor series about the mean. That is

$$R_C(x,y) = \left(1 + \frac{3S_n^2}{10} + \frac{S_n^3}{7} + \frac{3S_n^4}{8} + \frac{9S_n^5}{22}\right) \Big/ \sqrt{\mu_n}.$$

The truncation error involved in using this approximation is bounded by $16|S_n|^6/(1-2|S_n|)$ and the recursive process is stopped when S_n is small enough for this truncation error to be

```
negligible compared to the machine precision.

Within the domain of definition, the function value is itself
representable for all representable values of its arguments.
However, for values of the arguments near the extremes the above
algorithm must be modified so as to avoid causing underflows or
overflows in intermediate steps. In extreme regions arguments are
pre-scaled away from the extremes and compensating scaling of the
result is done before returning to the calling program.

      Third Kind. Math. Comput. 51 267--280.

5. Parameters

 1:  X -- DOUBLE PRECISION                                 Input

 2:  Y -- DOUBLE PRECISION                                 Input
     On entry: the arguments x and y of the function,
     respectively. Constraint: X >= 0.0 and Y /= 0.0.

 3:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry X < 0.0; the function is undefined.

IFAIL= 2
     On entryY = 0.0; the function is undefined.
```

```
          On soft failure the routine returns zero.

     7. Accuracy

     In principle the routine is capable of producing full machine
     precision. However round-off errors in internal arithmetic will
     result in slight loss of accuracy. This loss should never be
     excessive as the algorithm does not involve any significant
     amplification of round-off error. It is reasonable to assume that
     the result is accurate to within a small multiple of the machine
     precision.

     8. Further Comments

     Users should consult the Chapter Introduction which shows the
     relationship of this function to the classical definitions of the
     elliptic integrals.

     9. Example

     This example program simply generates a small set of non-extreme
     arguments which are used with the routine to produce the table of
     low accuracy results.

     The example program is not reproduced here. The source code for
     all example programs is distributed with the NAG Foundation
     Library software and should be available on-line.

S21BBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S21BBF returns a value of the symmetrised elliptic integral of the first kind, via the routine name.

2. Specification

```
      DOUBLE PRECISION FUNCTION S21BBF (X, Y, Z, IFAIL)
      INTEGER          IFAIL
      DOUBLE PRECISION X, Y, Z
```

3. Description

This routine calculates an approximation to the integral

$$R_F(x,y,z)=\frac{1}{2}\int_0^{\infty}\frac{dt}{\sqrt{(t+x)(t+y)(t+z)}}$$

where x, y, $z>=0$ and at most one is zero.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the rule:

$x_0=\min(x,y,z), z_0=\max(x,y,z)$,

y_0 = remaining third intermediate value argument.

(This ordering, which is possible because of the symmetry of the function, is done for technical reasons related to the avoidance of overflow and underflow.)

$(\mu)_n = (x_n+y_n+3z_n)/3$

$X = (1-x)/(\mu)$

```
     n           n      n

    Y    =   (1-y )/(mu)
     n           n      n

    Z    =   (1-z )/(mu)
     n           n      n

    (lambda) =  /x y +  /y z +  /z x
           n \/  n n /  n n /  n n

    x    =   (x +(lambda) )/4
     n+1       n         n

    y    =   (y +(lambda) )/4
     n+1       n         n

    z    =   (z +(lambda) )/4
     n+1       n         n

(epsilon) =max(|X |,|Y |,|Z |) and the function may be
         n       n    n    n
approximated adequately by a 5th order power series:

                              (        2           )
                              (   E   E   3E E   E )
                        1     (    2   2    2 3   3)
            R (x,y,z)= --------(1- --+ --- -----+ --)
             F                (   10  24   44    14)
                       /(mu)
                     \/     n

where E =X Y +Y Z +Z X ,E =X Y Z .
       2  n n  n n  n n  3  n n n

The truncation error involved in using this approximation is
                    6
bounded by (epsilon) /4(1-(epsilon) ) and the recursive process
                    n              n
is stopped when this truncation error is negligible compared with
the machine precision.

Within the domain of definition, the function value is itself
representable for all representable values of its arguments.
However, for values of the arguments near the extremes the above
algorithm must be modified so as to avoid causing underflows or
overflows in intermediate steps. In extreme regions arguments are
pre-scaled away from the extremes and compensating scaling of the
```

```
result is done before returning to the calling program.

        S21BCF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S21BCF returns a value of the symmetrised elliptic integral of the second kind, via the routine name.

2. Specification

```
       DOUBLE PRECISION FUNCTION S21BCF (X, Y, Z, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X, Y, Z
```

3. Description

This routine calculates an approximate value for the integral

$$R_D(x,y,z)=\frac{3}{2}\int_0^{\infty}\frac{dt}{\sqrt{(t+x)(t+y)(t+z)^3}}$$

where x, y>=0, at most one of x and y is zero, and z>0.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the rule:

$$x_0 = x$$

$$y_0 = y$$

$$z_0 = z$$

$$(\mu)_n = (x_n+y_n+3z_n)/5$$

$$X = (1-x)/(\mu)$$

n n n

$$Y_n = (1-y_n)/(\mu)_n$$

$$Z_n = (1-z_n)/(\mu)_n$$

$$(\lambda)_n = \sqrt{x_n y_n} + \sqrt{y_n z_n} + \sqrt{z_n x_n}$$

$$x_{n+1} = (x_n + (\lambda)_n)/4$$

$$y_{n+1} = (y_n + (\lambda)_n)/4$$

$$z_{n+1} = (z_n + (\lambda)_n)/4$$

For n sufficiently large,

$$(\epsilon)_n = \max(|X_n|,|Y_n|,|Z_n|) \sim \left(\frac{1}{4}\right)^n$$

and the function may be approximated adequately by a 5th order power series $R_D(x,y,z) = 3 \sum_{m=0}^{n-1} \frac{4^{-m}}{(z_m+(\lambda)_n)\sqrt{z_m}} +$

$$\frac{4^{-n}}{\sqrt{(\mu)_n^3}}\left[1 + \frac{3}{7}S_n^{(2)} + \frac{1}{3}S_n^{(3)} + \frac{3}{22}\left(S_n^{(2)}\right)^2 + \frac{3}{11}S_n^{(4)} + \frac{3}{13}S_n^{(2)}S_n^{(3)} + \frac{3}{13}S_n^{(5)}\right]$$

where

$$S_n^{(m)} = \left(X_n^m + Y_n^m + 3Z_n^m\right)/2m.$$

```
The truncation error in this expansion is bounded by
               6
     3(epsilon)
               n
 ------------------- and the recursive process is terminated when

    /            3
   / (1-(epsilon) )
 \/              n
this quantity is negligible compared with the machine precision.
```

The routine may fail either because it has been called with arguments outside the domain of definition, or with arguments so extreme that there is an unavoidable danger of setting underflow or overflow.

```
                 -3/2
Note: R (x,x,x)=x    , so there exists a region of extreme
       D
arguments for which the function value is not representable.
```

5. Parameters

```
 1:  X -- DOUBLE PRECISION                                 Input

 2:  Y -- DOUBLE PRECISION                                 Input

 3:  Z -- DOUBLE PRECISION                                 Input
     On entry: the arguments x, y and z of the function.
     Constraint: X, Y >= 0.0, Z > 0.0 and only one of X and Y may
     be zero.

 4:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.
     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry either X or Y is negative, or both X and Y are
     zero; the function is undefined.

IFAIL= 2
     On entry Z <= 0.0; the function is undefined.

IFAIL= 3
     On entry either Z is too close to zero or both X and Y are
     too close to zero: there is a danger of setting overflow.

IFAIL= 4
     On entry at least one of X, Y and Z is too large: there is a
     danger of setting underflow.

     On soft failure the routine returns zero.

7. Accuracy

In principle the routine is capable of producing full machine
precision. However round-off errors in internal arithmetic will
result in slight loss of accuracy. This loss should never be
excessive as the algorithm does not involve any significant
amplification of round-off error. It is reasonable to assume that
the result is accurate to within a small multiple of the machine
precision.

8. Further Comments

Users should consult the Chapter Introduction which shows the
relationship of this function to the classical definitions of the
elliptic integrals.

9. Example

This example program simply generates a small set of non-extreme
arguments which are used with the routine to produce the table of
low accuracy results.

         1. Purpose

         S21BDF returns a value of the symmetrised elliptic integral of
         the third kind, via the routine name.

         2. Specification

                DOUBLE PRECISION FUNCTION S21BDF (X, Y, Z, R, IFAIL)
                INTEGER          IFAIL
                DOUBLE PRECISION X, Y, Z, R

         3. Description

         This routine calculates an approximation to the integral

                                    infty
```

$$R_J(x,y,z,\rho) = \frac{3}{2} \int_0 \frac{dt}{(t+\rho)\sqrt{(t+x)(t+y)(t+z)}}$$

where $x, y, z \ge 0$, $\rho \ne 0$ and at most one of x, y and z is zero.

If $p<0$, the result computed is the Cauchy principal value of the integral.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the rule:

$$x_0 = x$$

$$y_0 = y$$

$$z_0 = z$$

$$\rho_0 = \rho$$

$$\mu_n = (x_n + y_n + z_n + 2\rho_n)/5$$

$$X_n = (1 - x_n)/\mu_n$$

$$Y_n = (1 - y_n)/\mu_n$$

$$Z_n = (1 - z_n)/\mu_n$$

$$P_n = (1 - \rho_n)/\mu_n$$

$$\lambda_n = \sqrt{x_n y_n} + \sqrt{y_n z_n} + \sqrt{z_n x_n}$$

$$x_{n+1} = (x_n + \lambda_n)/4$$

$$y_{n+1} = (y_n + \lambda_n)/4$$

```
    z    =   (z +(lambda) )/4
     n+1       n         n

    (rho) =  ((rho) +(lambda) )/4
         n+1       n         n
                                              2
           [                                  ]
    (alpha) =[(rho) (  /x +  /y +  /z )+  /x y z ]
           n [     n \/  n /  n /  n  /  n n n]

                                 2
    (beta) = (rho) ((rho) +(lambda) )
          n       n      n        n

For n sufficiently large,

                                                  1
             (epsilon) =max(|X |,|Y |,|Z |,|P |)~ --
                      n       n    n    n    n     n
                                                  4

and the function may be approximated by a 5th order power series
                  n-1
                  --  -m
R (x,y,z,(rho))=3 >   4  R ((alpha) ,(beta) )
 J                --      C        m       m
                  m=0

      -n
     4      [   3 (2)  1 (3)  3   (2) 2  3  (4)  3  (2) (3)  3  (5)]
+ ---------[1+ -S   + -S   + --(S   ) + --S   + --S   S   + --S   ]
            [   7 n    3 n    22  n      11 n    13 n   n    13 n  ]
     /    3
    / (mu)
  \/      n

       (m)     m  m  m   m
where S    = (X +Y +Z +2P )/2m.
       n       n  n  n   n

The truncation error in this expansion is bounded by

          6    /             3
3(epsilon) /  / (1-(epsilon) )  and the recursion process is
          n \/              n
terminated when this quantity is negligible compared with the
machine precision. The routine may fail either because it has
```

been called with arguments outside the domain of definition or with arguments so extreme that there is an unavoidable danger of setting underflow or overflow.

Note: $R_J(x,x,x,x)=x^{-\frac{3}{2}}$, so there exists a region of extreme arguments for which the function value is not representable.

5. Parameters

```
 1:  X -- DOUBLE PRECISION                                   Input

 2:  Y -- DOUBLE PRECISION                                   Input

 3:  Z -- DOUBLE PRECISION                                   Input

 4:  R -- DOUBLE PRECISION                                   Input
     On entry: the arguments x, y, z and (rho) of the function.
     Constraint: X, Y, Z >= 0.0, R /= 0.0 and at most one of X, Y
     and Z may be zero.

 5:  IFAIL -- INTEGER                                 Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).
```

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are

```
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry at least one of X, Y and Z is negative, or at least
     two of them are zero; the function is undefined.

IFAIL= 2
     On entry R = 0.0; the function is undefined.

IFAIL= 3
     On entry either R is too close to zero, or any two of X, Y
     and Z are too close to zero; there is a danger of setting
     overflow.

IFAIL= 4
     On entry at least one of X, Y, Z and R is too large; there
     is a danger of setting underflow.

IFAIL= 5
     An error has occurred in a call to S21BAF. Any such
     occurrence should be reported to NAG.

     On soft failure, the routine returns zero.

7. Accuracy

In principle the routine is capable of producing full machine
precision. However round-off errors in internal arithmetic will
result in slight loss of accuracy. This loss should never be
excessive as the algorithm does not involve any significant
amplification of round-off error. It is reasonable to assume that
the result is accurate to within a small multiple of the machine
precision.

8. Further Comments

Users should consult the Chapter Introduction which shows the
relationship of this function to the classical definitions of the
elliptic integrals.

If the argument R is equal to any of the other arguments, the
function reduces to the integral R , computed by S21BCF.
                                  D

9. Example

This example program simply generates a small set of non-extreme
arguments which are used with the routine to produce the table of
low accuracy results.
```

```
         The example program is not reproduced here. The source code for
         all example programs is distributed with the NAG Foundation
         Library software and should be available on-line.

                                    Chapter X01
                              Mathematical Constants

         1. Scope of the Chapter

         This chapter is concerned with the provision of mathematical
         constants required by other routines within the Library.

         It should be noted that because of the trivial nature of the
         routines individual routine documents are not provided.

         2. Background to the Problems

         Some Library routines require mathematical constants to maximum
         machine precision. These routines call Chapter X01 and thus
         lessen the number of changes that have to be made between
         different implementations of the Library.

         3. Recommendations on Choice and Use of Routines
```

```
          Although these routines are primarily intended for use by other
          routines they may be accessed directly by the user:

```

1. Scope of the Chapter

This chapter is concerned with parameters which characterise certain aspects of the computing environment in which the NAG Foundation Library is implemented. They relate primarily to floating-point arithmetic, but also to integer arithmetic and the elementary functions. The values of the parameters vary from one implementation of the Library to another, but within the context of a single implementation they are constants.

The parameters are intended for use primarily by other routines in the Library, but users of the Library may sometimes need to refer to them directly.

Each parameter-value is returned by a separate Fortran function. Because of the trivial nature of the functions, individual routine documents are not provided; the necessary details are given in Section 3 of this Introduction.

2. Background to the Problems

2.1. Floating-Point Arithmetic

2.1.1. A model of floating-point arithmetic

In order to characterise the important properties of floating-point arithmetic by means of a small number of parameters, NAG uses a simplified model of floating-point arithmetic. The parameters of the model can be chosen to provide a sufficiently close description of the behaviour of actual implementations of floating-point arithmetic, but not, in general, an exact description; actual implementations vary too much in the details of how numbers are represented or arithmetic operations are performed.

The model is based on that developed by Brown [1], but differs in some respects. The essential features are summarised here.

The model is characterised by four integer parameters and one logical parameter. The four integer parameters are:

b : the base

p : the precision (i.e. the number of significant base-B digits)

e_{min} : the minimum exponent

e : the maximum exponent

max

These parameters define a set of numerical values of the form:

$$f*b^{e}$$

where the exponent e must lie in the range $[e_{min},e_{max}]$, and the fraction f (also called the mantissa or significand) lies in the range [1/b,1), and may be written:

$$f=0.f_{1}f_{2}...f_{p}$$

Thus f is a p-digit fraction to the base b; the f_{i} are the base-b digits of the fraction: they are integers in the range 0 to b-1, and the leading digit f_{1} must not be zero.

The set of values so defined (together with zero) are called model numbers. For example, if b=10, p=5, e_{min}=-99 and e_{max}=+99, then a typical model number is $0.12345*10^{67}$.

The model numbers must obey certain rules for the computed results of the following basic arithmetic operations: addition, subtraction, multiplication, negation, absolute value, and comparisons. The rules depend on the value of the logical parameter ROUNDS.

If ROUNDS is true, then the computed result must be the nearest model number to the exact result (assuming that overflow or underflow does not occur); if the exact result is midway between two model numbers, then it may be rounded either way.

If ROUNDS is false, then: if the exact result is a model number, the computed result must be equal to the exact result; otherwise, the computed result may be either of the adjacent model numbers on either side of the exact result.

For division and square root, this latter rule is further relaxed (regardless of the value of ROUNDS): the computed result may also be one of the next adjacent model numbers on either side of the permitted values just stated.

On some machines, the full set of representable floating-point numbers conforms to the rules of the model with appropriate values of b, p, e_{min}, e_{max} and ROUNDS. For example, for machines with IEEE arithmetic, in double precision:

b = 2

p = 53

e_{min} =-1021

e_{max} =1024 and ROUNDS is true.

For other machines, values of the model parameters must be chosen which define a large subset of the representable numbers; typically it may be necessary to decrease p by 1 (in which case ROUNDS is always set to false), or to increase e_{min} or decrease e_{max} by a little bit. There are additional rules to ensure that arithmetic operations on those representable numbers which are not model numbers, are consistent with arithmetic on model numbers.

(Note: the model used here differs from that described in Brown [1] in the following respects: square-root is treated, like division, as a weakly supported operator; and the logical parameter ROUNDS has been introduced to take account of machines with good rounding.)

2.1.2. Derived parameters of floating-point arithmetic

Most numerical algorithms require access, not to the basic parameters of the model, but to certain derived values, of which the most important are:

the machine precision (epsilon): $= (\frac{1}{2})*b^{1-p}$ if ROUNDS is true,

$= b^{1-p}$ otherwise (but see Note below).

the smallest positive model number: $= b^{e_{min}-1}$

e

```
                              -p    max
the largest positive  =  (1-b  )*b
model number:

Note: this value is increased very slightly in some
implementations to ensure that the computed result of 1+(epsilon)
or 1-(epsilon) differs from 1. For example in IEEE binary single
                                           -24  -47
precision arithmetic the value is set to 2   +2   .

Two additional derived values are used in the NAG Foundation
Library. Their definitions depend not only on the properties of
the basic arithmetic operations just considered, but also on
properties of some of the elementary functions. We define the
safe range parameter to be the smallest positive model number z
such that for any x in the range [z,1/z] the following can be
computed without undue loss of accuracy, overflow, underflow or
other error:

    -x

    1/x

    -1/x

    SQRT(x)

    LOG(x)

    EXP(LOG(x))

    y**(LOG(x)/LOG(y)) for any y

In a similar fashion we define the safe range parameter for
complex arithmetic as the smallest positive model number z such
that for any x in the range [z,1/z] the following can be computed
without any undue loss of accuracy, overflow, underflow or other
error:

    -w

    1/w

    -1/w

    SQRT(w)

    LOG(w)

    EXP(LOG(w))
    y**(LOG(w)/LOG(y)) for any y

    ABS(w)
```

where w is any of x, ix, x+ix, 1/x, i/x, 1/x+i/x, and i is the square root of -1.

This parameter was introduced to take account of the quality of complex arithmetic on the machine. On machines with well implemented complex arithmetic, its value will differ from that of the real safe range parameter by a small multiplying factor less than 10. For poorly implemented complex arithmetic this factor may be larger by many orders of magnitude.

2.2. Other Aspects of the Computing Environment

No attempt has been made to characterise comprehensively any other aspects of the computing environment. The other functions in this chapter provide specific information that is occasionally required by routines in the Library.

3. Recommendations on Choice and Use of Routines

3.1. Parameters of Floating-point Arithmetic

```
DOUBLE PRECISION FUNCTION returns the machine precision i.e.
X02AJF()                  (1)  1-p                      1-p
                          (-)*b    if ROUNDS is true or b
                          (2)
                          otherwise (or a value very slightly
                          larger than this, see Section 2.1.2)

DOUBLE PRECISION FUNCTION returns the smallest positive model
X02AKF()                              e   -1
                                       min
                          number i.e. b

DOUBLE PRECISION FUNCTION returns the largest positive model
X02ALF()                                      e
                                         -p    max
                          number i.e. (1-b  )*b

DOUBLE PRECISION FUNCTION returns the safe range parameter as
```

```
X02AMF()                  defined in Section 2.1.2

DOUBLE PRECISION FUNCTION returns the safe range parameter for
X02ANF()                  complex arithmetic as defined in
                          Section 2.1.2

INTEGER FUNCTION X02BHF() returns the model parameter b

INTEGER FUNCTION X02BJF() returns the model parameter p

INTEGER FUNCTION X02BKF() returns the model parameter e
                                                      min

INTEGER FUNCTION X02BLF() returns the model parameter e
                                                      max

LOGICAL FUNCTION X02DJF() returns the model parameter ROUNDS
```

3.2. Parameters of Other Aspects of the Computing Environment

```
DOUBLE PRECISION FUNCTION returns the largest positive real
X02AHF(X)                 argument for which the SIN and COS
DOUBLE PRECISION X        routines return a result with some
                          meaningful accuracy

INTEGER FUNCTION X02BBF   returns the largest positive integer
(X)                       value
DOUBLE PRECISION X

INTEGER FUNCTION X02BEF   returns the maximum number of decimal
(X)                       digits which can be accurately
DOUBLE PRECISION X        represented over the whole range of
                          floating-point numbers
```

The argument X of these routines is a dummy argument.

4. Example Program Text

The example program simply prints the values of all the functions in Chapter X02. Obviously the results will vary from one implementation of the Library to another.

```

Chapter X04
Input/Output Utilities

1. Scope of the Chapter

This chapter contains utility routines concerned with input and output to or from an external file.

2. Background to the Problems

2.1. Output from NAG Foundation Library Routines

Output from NAG Foundation Library routines to an external file falls into two categories:

(a) Error messages which are always associated with an error exit from a routine, that is, with a non-zero value of IFAIL as specified in Section 6 of the routine document.

(b) Advisory messages which include output of final results, output of intermediate results to monitor the course of a computation, and various warning or informative messages.

Each category of output is written to its own Fortran output unit - the error message unit or the advisory message unit. In practice these may be the same unit number. Default unit numbers are provided for each implementation of the Library (see the Users' Note); they may be changed by users. Output of error messages may be controlled by the setting of IFAIL (see the Essential Introduction). Output of advisory messages may usually be controlled by the setting of some other parameter (e.g. MSGLVL) (or in some routines also by IFAIL). An alternative mechanism for completely suppressing output is to set the relevant unit number < 0.

For further information about error and advisory messages, see Chapter P01.

2.2. Matrix Printing Routines

Routines are provided to allow formatted output of general rectangular or triangular matrices stored in a two-dimensional array (real and complex data types).

All output is directed to the unit number for output of advisory messages, which may be altered by a call to X04ABF.

3. Recommendations on Choice and Use of Routines

Apart from the obvious utility of the matrix printing routines,

```
users of the Library may need to call routines in Chapter X04 for
the following purposes:

     if the default unit number for error messages (given in the
     Users' Note for your implementation) is not satisfactory,
     it may be changed to a new value NERR by the statement

           CALL X04AAF(1,NERR)

     Similarly the unit number for advisory messages may be
     changed to a new value NADV by the statement

           CALL X04ABF(1,NADV)

4. Index

Accessing unit number:
     of advisory message unit                                X04ABF
     of error message unit                                   X04AAF
Printing matrices:
     general complex matrix                                  X04DAF
     general real matrix                                     X04CAF

     X04AAF(3NAG)      Foundation Library (12/10/92)      X04AAF(3NAG)

          X04 -- Input/Output Utilities                              X04AAF
                  X04AAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          X04AAF returns the value of the current error message unit
          number, or sets the current error message unit number to a new
          value.

          2. Specification

                 SUBROUTINE X04AAF (IFLAG, NERR)
                 INTEGER          IFLAG, NERR

          3. Description

          This routine enables those library routines which output error
          messages, to determine the number of the output unit to which the
          error messages are to be sent; in this case X04AAF is called with
          IFLAG = 0. X04AAF may also be called with IFLAG = 1 to set the
          unit number to a specified value. Otherwise a default value
          (stated in the Users' Note for your implementation) is returned.

          Records written to this output unit by other library routines are
          at most 80 characters long (including a line-printer carriage
          control character).

          Note that if the unit number is set < 0, no messages will be
          output.

          4. References

          None.

          5. Parameters
          1:  IFLAG -- INTEGER                                       Input
              On entry: the action to be taken (see NERR). Constraint:
              IFLAG = 0 or 1.

          2:  NERR -- INTEGER                                 Input/Output
              On entry:
                   if IFLAG = 0, NERR need not be set;

                   if IFLAG = 1, NERR must specify the new error message
                   unit number.
              On exit:
                   if IFLAG = 0, NERR is set to the current error message
                   unit number,

                   if IFLAG = 1, NERR is unchanged.
              Note that Fortran unit numbers must be positive or zero. If
              NERR is set < 0, output of error messages is totally
              suppressed.

          6. Error Indicators and Warnings

          None.

          7. Accuracy

          Not applicable.

          8. Further Comments

          The time taken by the routine is negligible.

          9. Example

          In this example X04AAF is called by the user's main program to
          make the error message from the routine DUMMY appear on the same
          unit as the rest of the output (unit 6). Normally a NAG
          Foundation Library routine with an IFAIL parameter (see Essential
          Introduction) would take the place of DUMMY.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

16.7.5 Value of the current advisory message unit number

— nagx.ht —

```
\begin{page}{manpageXXx04abf}{NAG Documentation: x04abf}
\beginscroll
\begin{verbatim}

     X04ABF(3NAG)      Foundation Library (12/10/92)      X04ABF(3NAG)

          X04 -- Input/Output Utilities                           X04ABF
                  X04ABF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          X04ABF returns the value of the current advisory message unit
          number, or sets the current advisory message unit number to a new
          value.

          2. Specification

                 SUBROUTINE X04ABF (IFLAG, NADV)
                 INTEGER          IFLAG, NADV

          3. Description

          This routine enables those library routines which output advisory
          messages, to determine the number of the output unit to which the
          advisory messages are to be sent; in this case X04ABF is called
          with IFLAG = 0. X04ABF may also be called with IFLAG = 1 to set
          the unit number to a specified value. Otherwise a default value
          (stated in the User's Note for your implementation) is returned.

          Records written to this output unit by other library routines are
          at most 120 characters long (including a line-printer carriage
          control character), unless those library routines allow users to
          specify longer records.

          Note that if the unit number is set < 0, no messages will be
          output.
```

```
4. References

None.

5. Parameters

 1:  IFLAG -- INTEGER                                        Input
     On entry: the action to be taken (see NADV). Constraint:
     IFLAG = 0 or 1.

 2:  NADV -- INTEGER                                  Input/Output
     On entry:
          if IFLAG = 0, NADV need not be set;

          if IFLAG = 1, NADV must specify the new advisory
          message unit number.
     On exit:
          if IFLAG = 0, NADV is set to the current advisory
          message unit number;

          if IFLAG = 1, NADV is unchanged.
     Note that Fortran unit numbers must be positive or zero. If
     NADV is set < 0, output of advisory messages is totally
     suppressed.

6. Error Indicators and Warnings

None.

7. Accuracy

Not applicable.

8. Further Comments

The time taken by this routine is negligible.

9. Example

In this example X04ABF is called by the user's main program to
make the advisory message from the routine DUMMY appear on the
same unit as the rest of the output (unit 6). Normally a NAG
Foundation Library routine with an IFAIL parameter (see Essential
Introduction) would take the place of DUMMY.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

16.7.6 Print a real matrix stored in a two-dimensional array

— nagx.ht —

```
\begin{page}{manpageXXx04caf}{NAG Documentation: x04caf}
\beginscroll
\begin{verbatim}

     X04CAF(3NAG)      Foundation Library (12/10/92)      X04CAF(3NAG)

          X04 -- Input/Output Utilities                          X04CAF
                  X04CAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          X04CAF is an easy-to-use routine to print a real matrix stored in
          a two-dimensional array.

          2. Specification

                 SUBROUTINE X04CAF (MATRIX, DIAG, M, N, A, LDA, TITLE,
                1                   IFAIL)
                 INTEGER          M, N, LDA, IFAIL
                 DOUBLE PRECISION A(LDA,*)
                 CHARACTER*1      MATRIX, DIAG
                 CHARACTER*(*)    TITLE

          3. Description

          X04CAF prints a real matrix. It is an easy-to-use driver for
          X04CBF(*). The routine uses default values for the format in
          which numbers are printed, for labelling the rows and columns,
          and for output record length.
```

```
X04CAF will choose a format code such that numbers will be
printed with either an F8.4, F11.4 or a 1PE13.4 format. The F8.4
code is chosen if the sizes of all the matrix elements to be
printed lie between 0.001 and 1.0. The F11.4 code is chosen if
the sizes of all the matrix elements to be printed lie between 0.
001 and 9999.9999. Otherwise the 1PE13.4 code is chosen.

The matrix is printed with integer row and column labels, and
with a maximum record length of 80.

The matrix is output to the unit defined by X04ABF.

4. References

None.

5. Parameters

 1:  MATRIX -- CHARACTER*1                                   Input
     On entry: indicates the part of the matrix to be printed, as
     follows:

     MATRIX = 'G' (General), the whole of the rectangular matrix.

     MATRIX = 'L' (Lower), the lower triangle of the matrix, or
     the lower trapezium if the matrix has more rows than
     columns.

     MATRIX = 'U' (Upper), the upper triangle of the matrix, or
     the upper trapezium if the matrix has more columns than
     rows. Constraint: MATRIX must be one of 'G', 'L' or 'U'.

 2:  DIAG -- CHARACTER*1                                     Input
     On entry: unless MATRIX = 'G', DIAG must specify whether the
     diagonal elements of the matrix are to be printed, as
     follows:

     DIAG = 'B' (Blank), the diagonal elements of the matrix are
     not referenced and not printed.

     DIAG = 'U' (Unit diagonal), the diagonal elements of the
     matrix are not referenced, but are assumed all to be unity,
     and are printed as such.

     DIAG = 'N' (Non-unit diagonal), the diagonal elements of the
     matrix are referenced and printed.

     If MATRIX = 'G', then DIAG need not be set. Constraint: If
     MATRIX /= 'G', then DIAG must be one of 'B', 'U' or 'N'.
 3:  M -- INTEGER                                          Input

 4:  N -- INTEGER                                          Input
     On entry: the number of rows and columns of the matrix,
     respectively, to be printed.

     If either of M or N is less than 1, X04CAF will exit
     immediately after printing TITLE; no row or column labels
     are printed.

 5:  A(LDA,*) -- DOUBLE PRECISION array                    Input
     Note: the second dimension of the array A must be at least
     max(1,N).
     On entry: the matrix to be printed. Only the elements that
     will be referred to, as specified by parameters MATRIX and
     DIAG, need be set.

 6:  LDA -- INTEGER                                        Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which X04CAF is called.
     Constraint: LDA >= M.

 7:  TITLE -- CHARACTER*(*)                                Input
     On entry: a title to be printed above the matrix. If TITLE =
     ' ', no title (and no blank line) will be printed.

     If TITLE contains more than 80 characters, the contents of
     TITLE will be wrapped onto more than one line, with the
     break after 80 characters.

     Any trailing blank characters in TITLE are ignored.

 8:  IFAIL -- INTEGER                               Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
```

```
          On entry MATRIX /= 'G', 'L' or 'U'.

     IFAIL= 2
          On entry MATRIX = 'L' or 'U', but DIAG /= 'N', 'U' or 'B'.

     IFAIL= 3
          On entry LDA < M.

     7. Accuracy

     Not applicable.

     8. Further Comments

     A call to X04CAF is equivalent to a call to X04CBF(*) with the
     following argument values:

           NCOLS = 80
           INDENT = 0
           LABROW = 'I'
           LABCOL = 'I'
           FORMAT = ' '

     9. Example

     This example program calls X04CAF twice, first to print a 3 by 5
     rectangular matrix, and then to print a 5 by 5 lower triangular
     matrix.

     The example program is not reproduced here. The source code for
     all example programs is distributed with the NAG Foundation
     Library software and should be available on-line.

                  X04DAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          X04DAF is an easy-to-use routine to print a complex matrix stored
          in a two-dimensional array.

          2. Specification

                 SUBROUTINE X04DAF (MATRIX, DIAG, M, N, A, LDA, TITLE,
                1                   IFAIL)
                 INTEGER              M, N, LDA, IFAIL
                 COMPLEX(KIND(1.0D0)) A(LDA,*)
                 CHARACTER*1          MATRIX, DIAG
                 CHARACTER*(*)        TITLE

          3. Description

          X04DAF prints a complex matrix. It is an easy-to-use driver for
          X04DBF(*). The routine uses default values for the format in
          which numbers are printed, for labelling the rows and columns,
          and for output record length.

          X04DAF will choose a format code such that numbers will be
          printed with either an F8.4, F11.4 or a 1PE13.4 format. The F8.4
          code is chosen if the sizes of all the matrix elements to be
          printed lie between 0.001 and 1.0. The F11.4 code is chosen if
          the sizes of all the matrix elements to be printed lie between 0.
          001 and 9999.9999. Otherwise the 1PE13.4 code is chosen. The
          chosen code is used to print each complex element of the matrix
          with the real part above the imaginary part.

          The matrix is printed with integer row and column labels, and
          with a maximum record length of 80.

          The matrix is output to the unit defined by X04ABF.
```

```
4. References

None.

5. Parameters

 1:  MATRIX -- CHARACTER*1                                   Input
     On entry: indicates the part of the matrix to be printed, as
     follows:

     MATRIX = 'G' (General), the whole of the rectangular matrix.

     MATRIX = 'L' (Lower), the lower triangle of the matrix, or
     the lower trapezium if the matrix has more rows than
     columns.

     MATRIX = 'U' (Upper), the upper triangle of the matrix, or
     the upper trapezium if the matrix has more columns than
     rows. Constraint: MATRIX must be one of 'G', 'L' or 'U'.

 2:  DIAG -- CHARACTER*1                                     Input
     On entry: unless MATRIX = 'G', DIAG must specify whether the
     diagonal elements of the matrix are to be printed, as
     follows:

     DIAG = 'B' (Blank), the diagonal elements of the matrix are
     not referenced and not printed.

     DIAG = 'U' (Unit diagonal), the diagonal elements of the
     matrix are not referenced, but are assumed all to be unity,
     and are printed as such.

     DIAG = 'N' (Non-unit diagonal), the diagonal elements of the
     matrix are referenced and printed.

     If MATRIX = 'G', then DIAG need not be set. Constraint: If
     MATRIX /= 'G', then DIAG must be one of 'B', 'U' or 'N'.

 3:  M -- INTEGER                                            Input

 4:  N -- INTEGER                                            Input
     On entry: the number of rows and columns of the matrix,
     respectively, to be printed.

     If either of M or N is less than 1, X04DAF will exit
     immediately after printing TITLE; no row or column labels
     are printed.

 5:  A(LDA,*) -- COMPLEX(KIND(1.0D)) array                   Input
```

```
     Note: the second dimension of the array A must be at least
     max(1,N).
     On entry: the matrix to be printed. Only the elements that
     will be referred to, as specified by parameters MATRIX and
     DIAG, need be set.

 6:  LDA -- INTEGER                                       Input
     On entry:
     the first dimension of the array A as declared in the
     (sub)program from which X04DAF is called.
     Constraint: LDA >= M.

 7:  TITLE -- CHARACTER*(*)                               Input

     On entry: a title to be printed above the matrix. If TITLE =
     ' ', no title (and no blank line) will be printed.

     If TITLE contains more than 80 characters, the contents of
     TITLE will be wrapped onto more than one line, with the
     break after 80 characters.

     Any trailing blank characters in TITLE are ignored.

 8:  IFAIL -- INTEGER                              Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry MATRIX /= 'G', 'L' or 'U'.

IFAIL= 2
     On entry MATRIX = 'L' or 'U', but DIAG /= 'N', 'U' or 'B'.

IFAIL= 3
     On entry LDA < M.

7. Accuracy

Not applicable.
```

```
          8. Further Comments

          A call to X04DAF is equivalent to a call to X04DBF(*) with the
          following argument values:

                NCOLS = 80
                INDENT = 0
                LABROW = 'I'
                LABCOL = 'I'
                FORMAT = ' '
                USEFRM = 'A'

          9. Example

          This example program calls X04DAF twice, first to print a 4 by 3
          rectangular matrix, and then to print a 4 by 4 lower triangular
          matrix.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

```

```
                          Chapter X05
                    Date and Time Utilities

     1. Scope of the Chapter

     This chapter provides routines to obtain the current real time,
     and the amount of processor time used.

     2. Background to the Problems

     2.1. Real Time

     Routines are provided to obtain the current time in two different
     formats, and to compare two such times.

     2.2. Processor Time

     A routine is provided to return the current amount of processor
     time used. This allows the timing of a particular routine or
     section of code.

     3. Recommendations on Choice and Use of Routines

     X05AAF     returns the current date/time in integer format.

     X05ABF     converts from integer to character string date/time.

     X05ACF     compares two date/time character strings.

     X05BAF     returns the amount of processor time used.

     X05 -- Date and Time Utilities                Contents -- X05
     Chapter X05

     Date and Time Utilities

     X05AAF  Return date and time as an array of integers

     X05ABF  Convert array of integers representing date and time to
             character string

     X05ACF  Compare two character strings representing date and time

     X05BAF  Return the CPU time

\begin{verbatim}

     X05AAF(3NAG)      Foundation Library (12/10/92)      X05AAF(3NAG)

          X05 -- Date and Time Utilities                            X05AAF
                  X05AAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          X05AAF returns the current date and time.

          2. Specification

                 SUBROUTINE X05AAF (ITIME)
                 INTEGER          ITIME(7)

          3. Description

          X05AAF returns the current date and time as a set of seven
          integers.

          4. References

          None.

          5. Parameters

           1:  ITIME(7) -- INTEGER array                              Output
               On exit: the current date and time, as follows:

               ITIME(1) contains the current year.
               ITIME(2) contains the current month, in the range 1--12.

               ITIME(3) contains the current day, in the range 1--31.

               ITIME(4) contains the current hour, in the range 0--23.

               ITIME(5) contains the current minute, in the range 0--59.

               ITIME(6) contains the current second, in the range 0--59.

               ITIME(7) contains the current millisecond, in the range 0--
               999.

          6. Error Indicators and Warnings

          None.

          7. Accuracy

          The accuracy of this routine depends on the accuracy of the host
          machine. In particular, on some machines it may not be possible
          to return a value for the current millisecond, for example. In
          this case, the value returned will be zero.

          8. Further Comments

          None.

          9. Example

          This program prints out the vector ITIME after a call to X05AAF.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

16.7.10 From seven-integer format time and date to character string

— nagx.ht —

```
\begin{page}{manpageXXx05abf}{NAG Documentation: x05abf}
\beginscroll
\begin{verbatim}

     X05ABF(3NAG)      Foundation Library (12/10/92)      X05ABF(3NAG)

          X05 -- Date and Time Utilities                             X05ABF
                  X05ABF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          X05ABF converts from a seven-integer format time and date, as
          returned by X05AAF, into a character string, returned via the
          routine name.

          2. Specification

                 CHARACTER*30 FUNCTION X05ABF (ITIME)
                 INTEGER          ITIME(7)

          3. Description

          X05ABF returns a character string of length 30 which contains the
          date and time as supplied in argument ITIME. On exit, the
          character string has the following format:

                'DAY XXTH MTH YEAR HR:MN:SC.MIL',

            where  DAY   is one of 'Sun', 'Mon', 'Tue', 'Wed', 'Thu',
                         'Fri', 'Sat',

                   XX    is an integer denoting the day of the month,

                   TH    is one of 'st', 'nd', 'rd', 'th',

                   MTH   is one of 'Jan', 'Feb', 'Mar', 'Apr', 'May',
                         'Jun', 'Jul', 'Aug', 'Sep', 'Oct', 'Nov', 'Dec',

                   YEAR  is the year as a four digit integer,
                   HR    is the hour,

                   MN    is the minute,

                   SC    is the second,

                   MIL   is the millisecond.

          If on entry the date in ITIME is invalid, the string returned is

          4. References

          None.

          5. Parameters

           1:  ITIME(7) -- INTEGER array                              Input
               On entry: a date and time in the format returned by X05AAF,
               as follows:
                   ITIME   must contain the year as a positive integer.
                   (1)

                   ITIME   must contain the month, in the range 1-12.
                   (2)

                   ITIME   must contain the day, in the range 1 to p, where
                   (3)     p = 28, 29, 30 or 31, depending on the month and
                           year.

                   ITIME   must contain the hour, in the range 0-23.
                   (4)

                   ITIME   must contain the minute, in the range 0-59.
                   (5)

                   ITIME   must contain the second, in the range 0-59.
                   (6)

                   ITIME   must contain the millisecond, in the range 0-
                   (7)     999.

          6. Error Indicators and Warnings

          None.

          7. Accuracy

          The day name included as part of the character string returned by
          this routine is calculated assuming that the date is part of the
```

```
          Gregorian calendar. This calendar has been in operation in Europe
          since October the 15th 1582, and in Great Britain since September
          the 14th 1752. Entry to this routine with a date earlier than
          these will therefore not return a day name that is historically
          accurate.

          8. Further Comments

          Two dates stored in character string format, as returned by this
          routine, may be compared by X05ACF.

          9. Example

          This program initialises a time in ITIME, and converts it to
          character format by a call to X05ABF.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

———-

16.7.11 Compares two date/time character strings

— nagx.ht —

```
\begin{page}{manpageXXx05acf}{NAG Documentation: x05acf}
\beginscroll
\begin{verbatim}

     X05ACF(3NAG)      Foundation Library (12/10/92)      X05ACF(3NAG)

          X05 -- Date and Time Utilities                            X05ACF
                  X05ACF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.
```

```
1. Purpose

X05ACF compares two date/time character strings, each stored in
the format returned by X05ABF.

2. Specification

       INTEGER FUNCTION X05ACF (CTIME1, CTIME2)
       CHARACTER*(*)    CTIME1, CTIME2

3. Description

X05ACF compares two date/time character strings, and returns an
integer that specifies which one is the earliest. The result is
an integer returned through the routine name, with meaning as
follows:

     X05ACF = -1: the first date/time string is earlier than the
     second.

     X05ACF = 0: the two date/time strings are equivalent.

     X05ACF = 1: the first date/time string is later than the
     second.

4. References

None.

5. Parameters

 1:  CTIME1 -- CHARACTER*(*)                                Input

 2:  CTIME2 -- CHARACTER*(*)                                Input
     On entry: the date/time strings to be compared. These are
     expected be in the format returned by X05ABF, although
     X05ACF will still attempt to interpret the strings if they
     vary slightly from this format. See Section 8 for further
     details.

6. Error Indicators and Warnings

None.

7. Accuracy

Not applicable.

8. Further Comments
```

```
          For flexibility, X05ACF will accept various formats for the two
          date/time strings CTIME1 and CTIME2.

          The strings do not have to be the same length. It is permissible,
          for example, to enter with one or both of the strings truncated
          to a smaller length, in which case missing fields are treated as
          zero.

          Each character string may be of any length, but everything after
          character 80 is ignored.

          Each string may or may not include an alphabetic day name, such
          as 'Wednesday', at its start. These day names are ignored, and no
          check is made that the day name corresponds correctly to the rest
          of the date.

          The month name may contain any number of characters provided it
          uniquely identifies the month, however all characters that are
          supplied are significant.

          Each field in the character string must be separated by one or
          more spaces.

          The case of all alphabetic characters is insignificant.

          Any field in a date time string that is indecipherable according
          to the above rules will be converted to a zero value internally.
          Thus two strings that are completely indecipherable will compare
          equal.

          According to these rules, all the following date/time strings are
          equivalent:

              'Thursday 10th July 1958 12:43:17.320'

              'THU 10th JULY 1958 12:43:17.320'

              '10th Jul 1958 12:43:17.320'

          9. Example

          This program initialises two date/time strings, and compares them
          by a call to X05ACF.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

```

———

16.7.12 Amount of processor time used

— nagx.ht —

```
\begin{page}{manpageXXx05baf}{NAG Documentation: x05baf}
\beginscroll
\begin{verbatim}

     X05BAF(3NAG)      Foundation Library (12/10/92)      X05BAF(3NAG)

          X05 -- Date and Time Utilities                             X05BAF
                  X05BAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          X05BAF returns the amount of processor time used since an
          unspecified previous time, via the routine name.

          2. Specification

                 DOUBLE PRECISION FUNCTION X05BAF ()

          3. Description

          X05BAF returns the number of seconds of processor time used since
          some previous time. The previous time is system dependent, but
          may be, for example, the time the current job or the current
          program started running.

          If the system clock of the host machine is inaccessible for any
          reason, X05BAF returns the value zero.

          4. References
          None.

          5. Parameters

          None.

          6. Error Indicators and Warnings

          None.

          7. Accuracy

          The accuracy of the value returned depends on the accuracy of the
          system clock on the host machine.

          8. Further Comments

          Since the value returned by X05BAF is the amount of processor
          time since some unspecified earlier time, no significance should
          be placed on the value other than as a marker to be compared with
          some later figure returned by X05BAF. The amount of processor
          time that has elapsed between two calls of X05BAF can be simply
          calculated as the earlier value subtracted from the later value.

          9. Example

          This program makes a call to X05BAF, performs some computations,
          makes another call to X05BAF, and gives the time used by the
          computations as the difference between the two returned values.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

\vspace{-30}\horizontalline
In applied mathematics, electronic and chemical engineering, the
modelling process can produce a number of mathematical problems which
require numerical solutions for which symbolic methods are either not
possible or not obvious.  With the plethora of numerical library
routines for the solution of these problems often the numerical
analyst has to answer the question {\em Which routine to choose?}
\blankline
Some analysis needs to be carried out before the appropriate routine
can be identified i.e. {\em How stiff is this ODE?} and {\em Is this
function continuous?}  It may well be the case that more than one
routine is applicable to the problem.  So the question may become {\em
Which is likely to be the best?}  Such a choice may be critical for
both accuracy and efficiency.
\blankline
An expert system is thus required to make this choice based on the
result of its own analysis of the problem, call the routine and act on
the outcome.  This may be to put the answer in a relevant form or
react to an apparent failure of the chosen routine and thus choose and
call an alternative.  It should also have sufficient explanation
mechanisms to inform on the choice of routine and the reasons for that
choice.

```
\begin{page}{UXANNAIntro}{Introduction to the Axiom/NAG Expert System}
\begin{scroll}
\centerline{\tt\inputbitmap{\htbmdir{}/anna_logo.xbm}\rm}
\vspace{-30}\horizontalline
Deciding amongst, and then implementing, several possible approaches
to solving a numerical problem can be daunting for a novice user, or
tedious for an expert.  Different attributes of the problem need to be
identified and their possible interactions weighed up before a final
decision about which method to use can be made.
\blankline
The implementation is then largely an automatic, if laborious, process
of writing, compiling and linking usually Fortran code.  The aim is to
build an expert system which will use computer algebra to analyse such
features of a problem, inference mechanisms and a knowledge base to
choose a numerical method appropriate to the solution of a given
problem.
\blankline
Any interactive system is constrained by the need to provide a
reasonable response time for the user.  Given the complexity of some
of the analysis our system will need to do, it is clear that we should
only aim to select a good method, rather than try to identify the best
one available.  The overall goal is to provide a ‘‘black-box’’
interface to numerical software which allows non-experts access to its
full potential.  It will also provide explanation mechanisms
commensurate with its role as a teaching aid.
\blankline
Given, say, an integration to perform (which may or may not be able to be
handled symbolically), the system should choose and apply an appropriate
method, thus mirroring as closely as possible the way that an experienced
numerical analyst would think so, for example, given an integration to
perform:\newline
{\it \centerline{\inputbitmap{\htbmdir{}/int1.xbm}}}
\newline
the experienced analyst would see that the integral is semi-infinite and
transform it by splitting the range and transforming the integral over {\it
[1,\inputbitmap{\htbmdir{}/infty.xbm}]} into an integral over
{\it [0,1] } using the transformation {\it x -> 1/t}.
A different numerical routine might be used over each
sub-region and the results added to give the final answer.
\blankline
```

```
It then requires
the translation of the problem into Fortran code which may be extensive.
Even with this simple example, the process is quite involved.
\blankline

18.1.12 Example using the Axiom/NAG Expert System

⇒ "notitle" (UXANNAEx2) 18.1.13 on page 3947

— **annaex.ht** —

```
\begin{page}{UXANNAEx}{Example using the Axiom/NAG Expert System}
\begin{scroll}
\xtc{
{\bf Example 1}: The integral
{\centerline{\inputbitmap{\htbmdir{}/int1.xbm}}}
\newline
is performed as follows:
\blankline
}{}
\xtc{
}{
\spadpaste{ans :=
integrate((exp(-X^3)+exp(-3*X^2))/sqrt(X),0.0..\%plusInfinity)
\bound{ans} }
}
\blankline
\xtc{
It creates a composite structure for which the field containing
the result can be
expanded as required.\blankline
}{
\spadpaste{ans . 'result\free{ans}}
}
\blankline
\xtc{
}{
\spadpaste{ans . 'abserr\free{ans}}
}
```

```
\blankline
This system has performed the analysis described above, done the
necessary problem transformation, written any necessary Fortran,
called two different numerical routines, and amalgamated their
results.  This whole process was transparent to the user.

\begin{scroll}
\blankline
Some features are either present or absent in a problem.  Examples of
such binary decisions include {\em is a matrix symmetric?} and {\em is
a function continuous?}  However in practice many questions are about
the {\em degree} to which a problem exhibits a property: {\em how much
does a function oscillate?}, or {\em how stiff are these differential
equations?}
\blankline
We have therefore created decision agents of two types, reflecting
their property --- {\em Binary Agents} are Boolean functions returning
either true or false and {\em Intensity Functions} are quantitative
and return a range of different values, either numerical or structured
types. The framework we are developing is able to deal with both these
forms of information.
\blankline

In any given problem area (for example solving ordinary differential
equations, optimization etc.) we have a selection of {\em methods}.
These might be to use a particular NAG routine, or they might involve
employing a higher-level strategy such as transforming the problem
```

```
into an equivalent, but easier to solve, form.
\blankline
Associated with every method we define a {\em measure function} which
assesses the suitability of that method to a particular problem.  Each
measure function has access to a range of symbolic {\em agents} which
can answer questions about the various properties of the problem in
hand.

```
\begin{page}{UXANNAInfer}{Inference Mechanisms}
\begin{scroll}
\blankline
The inference machine will take the problem description as provided by
the user and perform an initial analysis to verify its validity.  It
will consider, in turn, all of the available methods within its
knowledge base which might solve that problem.  In doing so it
analyses the input problem to find out about any attributes that could
affect the ability of the methods under consideration to perform
effectively.
\blankline
Some of these measures may use lazy evaluation in the sense that, if a
method already assessed is believed to be a good candidate, and if
evaluating the current measure will be relatively expensive, then that
measure will not be evaluated unless later evidence shows that the
selected method is not, in fact, a successful strategy, for example if
it has failed.

```
\begin{page}{UXANNAMeth}{Method Domains}
\begin{scroll}
\blankline
An Axiom {\em domain} has been created for each method or strategy for
solving the problem.  These method domains each implement two
functions with a uniform (method independant) interface.  \blankline
{\bf measure:} A function which calculates an estimate of suitability
of this particular method to the problem if there is a possibility
that the method under consideration is more appropriate than one
already investigated.
\blankline
If it may be possible to improve on the current favourite method, the
function will call computational agents to analyse the problem for
specific features and calculate the measure from the results these
agents return, using a variation on the Lucks/Gladwell intensity and
compatibility model if conflict between attributes, as investigated by
these computational agents, may be present.
\blankline
{\bf implementation:} A function which may be one of two distinct
kinds.  The first kind uses the interface to the NAG Library to call a
particular routine with the required parameters.  Some of the
parameters may need to be calculated from the data provided before the
external function call.
\blankline
The other kind will apply a ‘‘high level’’ strategy to try to solve
the problem e.g.~a transformation of an expression from one that is
difficult to solve to one which is easier, or a splitting of the
problem into several more easily solvable parts.  For example, for a
solution of the equation above, since the integral is semi-infinite we
might wish to transform the range by, say, using the mapping
{\it y -> 1/x}
on the section {\it 1 < x < \inputbitmap{\htbmdir{}/infty.xbm}})
and adding the result to the unmapped section {\it 0 < x < 1}.
```

```
\blankline
\end{scroll}
\downlink{ Measure Functions }{UXANNAMeas}
\downlink{ Computational Agents }{UXANNAAgent}
\downlink{ Examples }{UXANNAEx}
\end{page}
```

———-

18.1.18 Measure Functions

⇒ "notitle" (UXANNAAgent) 18.1.19 on page 3953
⇒ "notitle" (UXANNAEx) 18.1.12 on page 3942
— **annaex.ht** —

```
\begin{page}{UXANNAMeas}{Measure Functions}
\begin{scroll}
\blankline
Each measure function will estimate the ability of a particular method to
solve a problem.  It will consult whichever agents are needed to perform
analysis on the problem in order to calculate the measure.  There is a
parameter which would contain the best compatibility
value found so far.
\blankline
However, the interpretation we give to the results of some tests is
not always clear-cut.  If a set of tests give conflicting advice as to
the appropriateness of a particular method, it becomes important to
decide not only {\it whether} certain properties are present but also
their {\it degree}.  This gives us a basis for estimating the
compatibility of each property.
\blankline
We have taken for our model the system recommended by Lucks and
Gladwell which uses a system of measurement of compatibility allowing
for interaction and conflict between a number of attributes.  All of
these processes may not be required if the choice is clear-cut e.g. we
have an integral to calculate which has a particular singularity
structure for which one particular method has been specifically
constructed.  However, for more difficult cases a composite picture
should be built up to calculate a true measurement.
\blankline
How the compatibility functions interpret the measurements of various
attributes is up to them and may vary between differing methods.  It
is this area that takes as its basis the {\it judgement} of Numerical
Analysis ‘experts’ whether that be from the documentation (which may
be deficient in certain respects) or from alternative sources.
However, its assessment of the suitability or otherwise of a
```

```
particular method is reflected in a single normalised value
facilitating the direct comparison of the suitability of a number of
possible methods.
\blankline
\end{scroll}
\downlink{ Computational Agents }{UXANNAAgent}
\downlink{ Examples }{UXANNAEx}
\end{page}
```

———-

18.1.19 Computational Agents

⇒ "notitle" (UXANNAEx) 18.1.12 on page 3942
— **annaex.ht** —

```
\begin{page}{UXANNAAgent}{Computational Agents}
\begin{scroll}
\blankline
Computational Agents are those program segments which investigate the
attributes of the input function or functions, such as {\bf
stiffnessAndStabilityOfODEIF} (the {\em IF} indicates that it is an
{\em Intensity Function} i.e. one that returns a normalised real
number or a set of normalised real numbers).  They are usually
functions or programs written completely in the Axiom language and
implemented using computer algebra.
\blankline
Some agents will be common to more than one problem domain whereas
others will be specific to a single domain.  They also vary greatly in
their complexity.  It is a fairly simple task to return details about
the range of a function since this information will have been included
in the problem specification.  It is a different order of complexity
to return details of its singularity structure.
\blankline
\xtc{
As an example, here is a call to the computational agent {\bf
singularitiesOf} to obtain the list of singularities of the function
{\it tan x} which are in the range
{\it 0..12\inputbitmap{\htbmdir{}/pi.xbm}}:
\blankline
}{
}
\xtc{
}{
\spadpaste{s := singularitiesOf(tan x,[x],0..12*\%pi)$ESCONT \free{lib3} }
}
\blankline
```

```
Each of these computational agents which may be called by a number of
method domains retain their output in a dynamic hash-table, so
speeding the process and retaining efficiency.
\end{scroll}

Chapter 20

Page hierarchy layout

This is the forest of pages in hyperdoc. Any page at the leftmost margin is a root page. Notice that the roots are disconnnected. The only reachable pages are those from the "RootPage" page below. All others exist but cannot be reached.

Indentation implies that a page can be reached by the less indented page.

Pages which have vertical bars or parens around them are lisp calls.

HYPER=${MNT}/${SYS}/doc
PAGEFILE=${HYPER}/bookvol7.1.pamphlet
SMAN=${MNT}/${SYS}/bin/sman
HTADD=${MNT}/${SYS}/bin/htadd

all: dir ${PAGEFILE} ${HYPER}/ht.db
	@echo 3 finished ${BOOK}

dir:
	@echo 0 making hypertex directories
	@mkdir -p ${WORK}
	@mkdir -p ${HYPER}
```

———-

Due to the awesome programming skills of Scott Morrison the htadd program will use the original source file in literate form to build the ht.db

— * —

```
${PAGEFILE}: ${BOOK}
	@echo 1 making ${PAGEFILE} from ${BOOK}
	@cp ${BOOK} ${PAGEFILE}

%:
	@echo 1 making ${HYPER}/$*.ht from ${BOOK}
	@ echo '(tangle "${BOOK}" "$*.ht" "${HYPER}/$*.ht")' | \
	  ${OBJ}/${SYS}/bin/lisp
```

———-

The patch/paste files are now included directly in bookvol7.1 Add new patch/paste files is a manual process when editing the book.

— * —

```
${HYPER}/ht.db: ${BOOK}
	@echo 2 making ${HYPER} from ${BOOK}
	@ (cd ${HYPER} ; \
	   rm -f ht.db ; \
	   ${HTADD} ${PAGEFILE} )
	@ cp -pr ${IN}/bitmaps ${HYPER}
	@ cp -pr ${IN}/viewports ${HYPER}
	@ (cd ${HYPER}/viewports ; \
for i in ‘find . -name "*.Z"‘ ; do gunzip $$i ; done )
```
